| <b>Northern Alternative Locations</b> | Consistent with the Block 2 Lease Agreement and exploration objectives. Supports fulfilment of minimum work programme commitments if drilled as Asopus-1. | Technically feasible, but seismic interpretation did not identify a clear geological advantage relative to 1A for the main exploration targets.                                                                                   | Unit well cost is expected to be similar to other alternative locations, with no demonstrable improvement in exploration success potential to justify selection over 1A.                     | Environmental impacts were not considered materially different between alternative locations as all options involved a single exploration well and similar offshore operating activities. Selection was therefore primarily based on geological and technical factors | <b>Not preferred.</b> No clear technical or geological advantage over 1A, and therefore not justified as the selected drilling location for Asopus-1.                                   |

## 7.2.3 Well Trajectory

Alternative well trajectories were considered for the Asopus-1 exploration well, including vertical, low- and high-inclination, and horizontal profiles. A vertical or low-inclination well trajectory was selected as the preferred option because it represents the shortest and simplest well path to the exploration target, thereby helping to reduce expected drilling time, energy use, emissions, and associated discharges (e.g. drill cuttings volume), while seabed disturbance is governed by the surface location and conductor installation rather than

the downhole trajectory. High-inclination and horizontal trajectories were rejected as they would increase well length and drilling complexity without providing environmental or technical benefit for the exploration objectives of a single well.

Table 7-2 summarises the well trajectory alternatives considered and the basis for selecting a vertical or low-inclination trajectory as the preferred option.

**Table 7-2: Summary of Well Trajectory Alternative Analysis**

| OPTION                                 | REGULATORY COMPATIBILITY                                                                                                        | TECHNICAL FEASIBILITY                                                                                                                                             | FINANCIAL FEASIBILITY                                                                                                                                                         | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                           | OVERALL ASSESSMENT                                                                                                                                                                     |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vertical / Low-Inclination Well</b> | Compatible with standard offshore drilling practices and regulatory requirements for exploration wells in Greek waters.         | Shortest and most direct path to the target from the proposed surface location. Well design is straightforward, with lower operational risk and complexity.       | Expected to be the most cost-efficient option due to reduced drilling duration, simpler equipment, and lower operational risk for the same exploration objective.             | Lower energy consumption, emissions, and drill-cuttings volume than with longer trajectories. Seabed disturbance is determined by surface installation and is similar across options. | <b>Preferred option.</b> Most efficient trajectory for an initial exploration well, offering the best balance of technical simplicity, cost control, and reduced operational duration. |
| <b>High-Inclination Well</b>           | Compatible with regulatory requirements but not required for this target geometry.                                              | Technically feasible but introduces unnecessary drilling complexity and increased well length without improving target access from the selected surface location. | Higher expected cost due to increased drilling time, specialised equipment, and operational complexity, with no corresponding improvement in exploration success probability. | Longer drilling duration increases energy use, emissions, and waste generation relative to the vertical option. Impact type is similar; magnitude is higher due to extended duration. | <b>Not preferred.</b> No technical or environmental advantage for this exploration target; adds unnecessary complexity and cost.                                                       |
| <b>Horizontal Well</b>                 | Compatible with regulatory requirements but generally applied to development or delineation scenarios, not initial exploration. | Technically feasible but unnecessarily complex for an initial exploration well where the target is directly beneath the surface location.                         | Higher expected cost and operational risk compared to a vertical well, with no additional exploration value for this objective.                                               | Longest drilling duration and highest energy use, emissions, and waste generation among the options. No environmental benefit to offset the increased footprint.                      | <b>Not preferred.</b> Inappropriate for an initial exploration well; would increase technical complexity, cost, and environmental burden without exploration benefit.                  |

## 7.2.4 Drilling Unit Type

Alternative drilling unit types were evaluated to identify a technically feasible option with the lowest practicable environmental and safety risk. Jack-up units were excluded due to water depth. Moored semi-submersible units were excluded because anchor deployment and associated anchor handling operations in deep water would introduce seabed disturbance and safety risks that are avoided by a dynamically positioned unit.

Dynamically positioned (DP) semi-submersible units were also considered. While they avoid anchor deployment, they typically offer significantly lower variable deck load (VDL) and storage capacity than a

drillship, which increases the frequency of supply vessel trips and associated marine traffic, emissions, and operational discharges. Their motion characteristics and operational momentum differ from those of a drillship, and they are generally less suited to the logistical and operational requirements of a deepwater exploration campaign of this scope.

A DP drillship was selected as the preferred option. It avoids anchor deployment and associated seabed disturbance, while offering significantly higher VDL and storage capacity, reducing logistics demand and marine traffic. The DP capability also allows faster transit and on-station positioning compared with both moored and DP semi-submersible alternatives, reducing standby time and associated emissions.

Energean acknowledges that a dynamically positioned (DP) mobile offshore drilling unit (MODU) generally has a higher fuel consumption than a moored unit. However, the overall environmental footprint is reduced by eliminating anchor handling, reducing logistics demand, and shortening positioning time. The avoidance of seabed disturbance from anchor systems and the reduction of associated safety risks in deep water were also principal factors in the selection.

For the Asopus-1 exploration well, the combination of environmental, safety, and operational efficiency considerations informed the selection of a drillship as the most appropriate option. The selected Stena DrillMAX drillship operates under an energy management plan that includes operational measures to manage fuel consumption and energy efficiency during drilling operations, subject to monitoring and verification under the Project environmental management system.

The selected DP drillship configuration also contributes to reducing operational and environmental risks through avoidance of anchor deployment and reduction of associated offshore activities, consistent with ALARP principles applied within offshore risk management processes.

Table 7-3 presents the alternative analysis underpinning the MODU selection.

**Table 7-3: Summary of MODU Alternative Analysis**

| OPTION                       | REGULATORY COMPATIBILITY                                           | TECHNICAL FEASIBILITY                                                                                                                                                                                     | FINANCIAL FEASIBILITY                                                                                                                                                 | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                         | OVERALL ASSESSMENT                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Drillship (DP)</b>        | Compatible with regulatory requirements for deepwater exploration. | Preferred for the water depth and offshore conditions. Avoids anchoring. High VDL and storage capacity reduce supply vessel frequency. Faster transit and positioning than semi-submersible alternatives. | Expected to be cost-efficient due to reduced logistics demand, shorter positioning time, and elimination of anchor handling, offsetting higher unit fuel consumption. | Avoids seabed disturbance from anchor deployment. Reduced marine traffic from fewer supply trips lowers associated emissions and discharges. Higher fuel consumption during drilling is managed through the energy management plan. | <b>Preferred alternative.</b> Selected based on operational efficiency, reduced seabed interaction, lower logistics demand, and suitability for deepwater conditions. |
| <b>Semi-submersible (DP)</b> | Compatible with regulatory requirements for deepwater exploration. | Technically feasible and avoids anchor deployment. However, significantly lower VDL and storage capacity than a                                                                                           | Comparable unit cost but higher logistics expenditure due to increased supply vessel trips and                                                                        | Avoids seabed disturbance from anchors but generates more marine traffic and associated emissions due to higher logistics                                                                                                           | <b>Not preferred.</b> Technically feasible but offers inferior logistical efficiency and operational characteristics                                                  |

| OPTION                                     | REGULATORY COMPATIBILITY                                                                                | TECHNICAL FEASIBILITY                                                                                                                                                       | FINANCIAL FEASIBILITY                                                                                                                              | ENVIRONMENTAL COMPATIBILITY                                                                                                                    | OVERALL ASSESSMENT                                                                                                                   |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
|                                            |                                                                                                         | drillship increases supply vessel frequency. Motion characteristics and operational momentum differ, making it less suited to the logistical requirements of this campaign. | potentially longer operational duration.                                                                                                           | demand. Fuel consumption characteristics differ but are not the determining factor.                                                            | compared to a drillship for this exploration campaign.                                                                               |
| <b>Semi-submersible MODU (Moored Unit)</b> | Compatible with regulatory requirements but constrained by seabed conditions and anchoring feasibility. | Technically viable but requires anchor deployment and handling in deep water. Mooring spread introduces operational complexity and safety considerations.                   | Higher expected costs due to anchor handling, installation, and retrieval operations. Additional support vessels increase operational expenditure. | Seabed disturbance from anchor deployment and recovery. Additional support vessels increase overall emissions and marine activity in the area. | <b>Not preferred.</b> Excluded due to increased seabed interaction, operational complexity, and safety considerations in deep water. |
| <b>Jack-up Rig</b>                         | Not applicable, as regulatory compliance cannot be demonstrated due to water depth limitations.         | Not feasible for 840 m water depth.                                                                                                                                         | Not viable.                                                                                                                                        | Not applicable.                                                                                                                                | <b>Not preferred.</b> Not feasible. Excluded due to water depth constraints.                                                         |

## 7.2.5 Drilling Strategy Sequence

Two alternative drilling strategy sequences were considered for the exploration of the Asopus-1 well: a single drilling campaign, in which all activities are completed during one mobilisation of the drilling unit, and a staged campaign, involving multiple mobilisations and demobilisations. A single drilling campaign was selected as the preferred option.

Compared to a staged approach, this strategy helps avoid repeated rig movements and associated marine and aviation logistics, thereby helping to reduce vessel traffic, fuel consumption, atmospheric emissions, and the overall duration of offshore activity. A staged drilling campaign was rejected because it would require additional rig moves and extended offshore presence, increasing cumulative environmental disturbance without providing environmental or technical benefit for a single exploration well.

Alternative drilling windows were reviewed during project planning. The selected campaign schedule was influenced by drilling unit availability, logistics requirements, and environmental considerations. Due to the temporary nature of the activity, offshore location, and implementation of proposed mitigation measures, no environmental advantage was identified that would justify restricting operations to an alternative seasonal window.

Table 7-4 summarises the assessment of drilling strategy alternatives and the basis for selecting a single campaign as the preferred option.

Table 7-4: Summary of Drilling Strategy Sequence Alternative Analysis

| OPTION                                          | REGULATORY COMPATIBILITY                                                                                               | TECHNICAL FEASIBILITY                                                                                                                                               | FINANCIAL FEASIBILITY                                                                                                                                         | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                  | OVERALL ASSESSMENT                                                                                                                                                               |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Single Drilling Campaign</b>                 | Compatible with applicable regulatory and permitting requirements for offshore exploration drilling.                   | Enables completion of all drilling activities during a single mobilisation, avoiding rig relocation between phases and reducing operational complexity.             | Expected to be more cost-efficient due to fewer mobilisation/demobilisation events, reduced logistics requirements, and shorter overall operational duration. | Minimises vessel traffic, fuel consumption, atmospheric emissions, and offshore activity duration by avoiding repeated rig moves and associated marine and aviation support operations.                                      | <b>Preferred alternative.</b> Reduces operational complexity and environmental footprint while ensuring efficient completion of exploration objectives in a single mobilisation. |
| <b>Staged Campaign (multiple mobilisations)</b> | Compatible with applicable regulatory requirements but operationally more complex due to repeated mobilisation events. | Technically feasible but requires repeated mobilisation and demobilisation of the drilling unit, increasing operational complexity and extending offshore presence. | Higher expected costs due to additional rig moves, extended offshore operations, and increased logistics demand.                                              | Results in increased vessel traffic, higher fuel consumption, greater atmospheric emissions, and prolonged offshore presence, leading to higher cumulative environmental disturbance without additional exploration benefit. | <b>Not preferred.</b> Technically feasible but increases environmental impacts and operational complexity without providing benefits for a single exploration well.              |

## 7.2.6 Drilling Fluids

Two drilling fluid system options were assessed for the Asopus-1 well:

1. Water-based mud with treated cuttings disposal to the sea.
2. Non-aqueous drilling fluid (NADF or SOBM) with either skip and ship or offshore clean-up/disposal to the sea.

The selected drilling fluid approach for Asopus-1 is Option 1, as outlined in Table 7-5. The selected approach uses water-based muds (WBMs), which provide sufficient operational flexibility to manage formation uncertainties and potential drilling contingencies during exploration activities, while also offering lower environmental risk for cuttings discharge and reduced requirements for cuttings handling, treatment, and transport to shore compared with NADF.

Although non-aqueous drilling fluids (NADFs) can offer improved drilling performance in certain formations and trajectories, particularly hydrate-bearing shales or directional wells, such conditions are not anticipated for the vertical well Asopus-1 well, and therefore NADFs are not proposed for use in this exploration campaign.

Table 7-5: Summary of Drilling Fluids Alternative Analysis

| OPTION                                               | REGULATORY COMPATIBILITY                                                                                                                                                                                                                                                                                                | TECHNICAL FEASIBILITY                                                                                                                                                                                                                                             | FINANCIAL FEASIBILITY                                                                                                                                  | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                                                                                   | OVERALL ASSESSMENT                                                                                                                                                             |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Water-Based Mud (WBM) Only</b>                    | Permitted under standard offshore discharge controls. WBM cuttings are discharged to the seabed in the riserless section and discharged from the rig during subsequent sections, subject to standard monitoring and compliance with Greek and EU offshore discharge requirements.                                       | Suitable for all sections of the well, including the riserless top hole where cuttings are discharged directly to the seabed. Provides sufficient operational flexibility for the vertical Asopus-1 trajectory and anticipated formations.                        | Lower cost profile due to single-fluid management, simpler waste handling, and no requirement for skip-and-ship or specialised containment systems.    | Lower environmental risk. WBM cuttings are discharged to the seabed in the riserless section and discharged from the rig during subsequent sections, with reduced toxicity and simpler waste management compared with NADF-based systems.                                                     | <b>Preferred alternative.</b><br>WBM is technically sufficient and regulatorily compliant for all sections of the Asopus-1 exploration well, including the riserless top hole. |
| <b>Non-Aqueous Drilling Fluid (NADF / SOBM Only)</b> | NADF is not proposed for the Asopus-1 well. Its use in the riserless top-hole section is incompatible with the planned drilling approach because cuttings are discharged directly to the seabed. Use of NADF below the mudline would require separate cuttings management measures and regulatory approval.             | Not feasible for the riserless top hole. High performance in specific formations below the mudline (e.g., reactive shales), but not required for the vertical Asopus-1 well where such conditions are not anticipated.                                            | Higher cost profile due to fluid management, handling, transportation and potential cuttings treatment requirements.                                   | Not feasible for the riserless section due to toxicity constraints on direct seabed discharge. Increased waste-management requirements and greater environmental management complexity compared with WBM systems. Any use would require additional controls and cuttings-management measures. | <b>Not preferred.</b><br>Not appropriate for Asopus-1 due to regulatory restrictions on discharge and absence of a technical requirement for NADF.                             |
| <b>Hybrid WBM / NADF (Section-Based Use)</b>         | Permitted under applicable offshore discharge controls. WBM cuttings are discharged to the seabed in the riserless section. For sections below the mudline where NADF is used, cuttings may be discharged or contained subject to compliance with the Offshore Protocol requirements and applicable discharge controls. | Standard industry practice. WBM is used for the riserless top hole section; NADF may be used for lower sections if specific formation conditions require it. For Asopus-1, the vertical trajectory and anticipated formations do not require NADF in any section. | Higher than WBM-only due to dual-system management, fluid transitions, and potential NADF cuttings handling, but standard where technically justified. | WBM discharge in the riserless section is manageable under standard controls. For NADF sections below the mudline, cuttings are subject to the Offshore Protocol requirements. Not justified here as WBM is sufficient throughout.                                                            | <b>Not preferred.</b><br>Standard industry practice but unnecessary for Asopus-1; WBM is technically sufficient for all sections including the riserless top hole.             |

Water-Based Mud (WBM) has been selected as the preferred drilling fluid system for the Asopus-1 exploration well due to lower toxicity and reduced waste management complexity, regulatory acceptability,

operational suitability for the anticipated geological conditions, and reduced waste handling and transportation requirements relative to non-aqueous drilling fluid systems.

## 7.2.7 Treatment/Disposal of Drilling Fluids and Cuttings

Alternative drilling fluid systems were considered for the Asopus-1 exploration well, including the use of water-based mud (WBM), non-aqueous drilling fluids (NADF), and hybrid systems.

The use of water-based mud (WBM) provides several technically feasible options for the management of drilling fluids and cuttings, as outlined in Table 7-6. Although the discharge of certain low toxicity non aqueous drilling fluid (NADF) cuttings may be permitted under the Barcelona Convention framework, NADF cannot be used in the riserless top hole section where cuttings are discharged directly to the seabed. For sections below the mudline, NADF use would involve additional handling, storage, transport, and waste management requirements, particularly during riserless drilling, resulting in increased lifecycle environmental impacts compared to WBM.

WBM was selected as the preferred drilling fluid system. It is compatible with both riserless and riser-based drilling and can be managed using established practices that minimise environmental exposure. In addition, for a single offshore exploration well, the limited volumes generated mean that discharge to sea using WBM is considered the most environmentally and economically proportionate option. This conclusion is consistent with international guidance on drill cuttings management<sup>58</sup>.

**Table 7-6: Summary of Fluids and Cuttings Disposal Alternative Analysis**

| OPTION                                                                         | REGULATORY COMPATIBILITY                                                                                                                                                                                          | TECHNICAL FEASIBILITY                                                                                                                          | FINANCIAL FEASIBILITY                                                                                        | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                       | OVERALL ASSESSMENT                                                                                                                              |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Water-Based Mud (WBM) with Cuttings Discharge to Sea</b>                    | Compliant with applicable offshore discharge regulations, including the Barcelona Convention, which permits disposal of WBM-associated cuttings at sea subject to solids control equipment and permit conditions. | Technically suitable for both riserless and riser-based operations; supported by established offshore practice for WBM handling and discharge. | Most cost-effective option, requiring minimal additional handling, storage, transport, or onshore treatment. | Cuttings discharge causes localised, temporary seabed disturbance; WBM systems minimise toxicity and persistence, and for a single exploration well the volumes involved make this the most proportionate option. | <b>Preferred alternative.</b> Best balance of compliance, operational simplicity, cost, and environmental impact for a single exploration well. |
| <b>Non-Aqueous Drilling Fluids (NADF) with Cuttings Management / Discharge</b> | Disposal of whole NADF fluid to sea is not permitted under any circumstance, consistent with the Barcelona Convention and                                                                                         | Not feasible for this project. NADF use is inherently tied to riserless-section application, which is already excluded on technical grounds    | Not applicable, as the option is excluded on technical grounds before cost considerations arise.             | Not applicable, as the option cannot be implemented at this well.                                                                                                                                                 | Not feasible for Asopus-1. This is a project-specific technical exclusion driven by the riserless-                                              |

IOGP Info Sheet "Use of Lifecycle Impact Assessments in drill cuttings waste management decisions".

| OPTION                                                               | REGULATORY COMPATIBILITY                                                                                                                                                                                            | TECHNICAL FEASIBILITY                                                                                                                                                                | FINANCIAL FEASIBILITY                                                                          | ENVIRONMENTAL COMPATIBILITY                                                                                                                             | OVERALL ASSESSMENT                                                                                                                                         |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                      | comparable international frameworks. NADF-associated cuttings could in principle be discharged if treated to residual oil content thresholds and approved by permit, but this pathway is not applicable at Asopus-1 | given the water depth at Asopus-1.                                                                                                                                                   |                                                                                                |                                                                                                                                                         | section limitation, not a categorical regulatory prohibition on NADF cuttings management generally.                                                        |
| <b>Offshore Reinjection of Cuttings and Fluids</b>                   | Compliant only where injection infrastructure exists and site-specific approval is granted; this precondition is not met at Asopus-1.                                                                               | Not feasible. No injection well or infrastructure exists in Block 2 or nearby to support reinjection from the drilling location.                                                     | Not feasible due to the absence of the required infrastructure.                                | Not applicable, as the option cannot be implemented.                                                                                                    | Not feasible. Excluded outright: no other well exists nearby to receive reinjected cuttings and fluids.                                                    |
| <b>Riserless Skip-and-Ship (Onshore Treatment of WBM Cuttings)</b>   | Regulatorily acceptable in principle under specific conditions, but not applicable given the technical restrictions.                                                                                                | Not feasible for this project. The absence of a riser system and the water depth approaching the operational limits of riserless mud recovery significantly constrain applicability. | Would require substantial additional logistics, vessel time, and waste transport arrangements. | Increased vessel movements, handling operations, and transport activities would result in higher emissions, noise, and lifecycle environmental impacts. | Not feasible. Operational constraints and water depth limitations make this option unsuitable for Asopus-1, not a rejection of skip-and-ship as a concept. |
| <b>Riser-Based Skip-and-Ship (Onshore Treatment of WBM Cuttings)</b> | Fully compliant where permitted under waste management and offshore discharge regulations.                                                                                                                          | Technically feasible, but requires continuous cuttings handling, storage, and transfer operations from the rig.                                                                      | Increased costs associated with waste handling, transport, and onshore treatment /disposal.    | Higher environmental footprint due to increased logistics, vessel activity, and waste transport compared with direct discharge options.                 | Not preferred. Technically feasible but introduces unnecessary logistical complexity and environmental burden for a single exploration well.               |

## 7.2.8 Cement Systems

Cementing is an essential component of well construction and abandonment, providing zonal isolation and long-term well integrity. For the Asopus-1 exploration well, alternatives for cement type and cementing approach were evaluated at the design stage, with the objective of ensuring well integrity and environmental protection while maintaining a proportionate footprint for a single offshore exploration well.

The assessment considered technically feasible and legally compliant options capable of meeting well objectives and permanent abandonment requirements. The main options and their evaluation are summarised in Table 7-7.

**Table 7-7: Summary of Cementing Systems Alternative Analysis**

| OPTION                                                                  | REGULATORY COMPATIBILITY                                                                                                                                | TECHNICAL FEASIBILITY                                                                                                                                                                                       | FINANCIAL FEASIBILITY                                                                                                                                               | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                                                                            | OVERALL ASSESSMENT                                                                                                                                                                                              |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Conventional Oilwell Cement Systems</b>                              | Compliant with applicable offshore well construction and abandonment regulations, and consistent with recognised industry standards for well integrity. | Proven technology with an extensive deepwater track record, providing reliable zonal isolation and long-term barrier integrity; predictable performance reduces the need for remedial cementing operations. | Supported by a mature supply chain and well-established operational procedures, enabling cost-effective implementation with low technical risk.                     | Cement production carries an inherent embodied carbon footprint, but reliable performance reduces the likelihood of remedial cementing, minimising overall material use and lifecycle impact; cement volumes will be optimised using logging and design verification to avoid overuse. | <b>Preferred alternative.</b><br>Provides the most robust and reliable solution for well integrity and abandonment while maintaining a proportionate footprint for a single exploration well.                   |
| <b>Alternative / Low-Carbon Cement Formulations</b>                     | Compliant where meeting applicable API and regulatory performance requirements, subject to acceptance by competent authorities on a case-by-case basis. | Limited field experience in deepwater exploration and abandonment conditions introduces uncertainty regarding long-term barrier performance compared with conventional systems.                             | Potentially higher material or supply costs, with possible additional costs for contingency remedial operations if barrier performance is not achieved as designed. | Lower embodied carbon during manufacture; however, an increased risk of leak due to loss of primary seal could require carbon-intensive remedial operations, offsetting the potential carbon benefit.                                                                                  | <b>Not preferred.</b><br>Offers potential carbon benefits, but limited operational track record in comparable deepwater conditions introduces additional technical uncertainty relative to conventional cement. |
| <b>Mechanical / Non-Cement Barrier Systems (Standalone Replacement)</b> | Not acceptable as a standalone solution under current offshore well integrity and abandonment regulatory frameworks.                                    | Not feasible. Mechanical barriers alone are not suitable to provide permanent zonal isolation over geological timescales or to meet primary and secondary barrier requirements.                             | Not feasible due to inability to satisfy regulatory well integrity requirements.                                                                                    | Not applicable, as the option cannot be implemented.                                                                                                                                                                                                                                   | <b>Not preferred.</b><br>Excluded as it cannot meet fundamental regulatory and technical requirements for permanent well barriers.                                                                              |

Based on this assessment, conventional oil-well cement systems have been selected as the primary cementing solution for Asopus-1. This option provides the highest level of assurance for well integrity and regulatory compliance while maintaining a proportionate environmental footprint. Cement volumes will be optimised using calliper-log data and design verification to minimise material use while ensuring effective zonal isolation and permanent abandonment, in line with recognised good industry practice and relevant well integrity standards (e.g. API Std 65-2).

## 7.2.9 Lighting

Lighting requirements for the drilling unit and support vessels were also considered. Offshore drilling operations are classified as restricted in their ability to manoeuvre (RAM), and lighting is therefore required to comply with COLREGS, SOLAS, and relevant Greek maritime safety legislation.

Reducing or modifying lighting beyond these requirements is not feasible, as it would compromise navigational safety, aviation operations, and effective enforcement of the 500 m safety zone. Standard, regulation-compliant lighting has therefore been selected as the only practicable option. Table 7-8 outlines the alternative analysis for the lighting.

**Table 7-8: Summary of Lighting Alternative Analysis**

| OPTION                                                                  | REGULATORY COMPATIBILITY                                                                                                                                                                    | TECHNICAL FEASIBILITY                                                                                                                                                                                 | FINANCIAL FEASIBILITY                                                                                                                                  | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                           | OVERALL ASSESSMENT                                                                                                                                                                            |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Standard MODU Lighting</b>                                           | Compliant with COLREGS, SOLAS, and applicable Greek maritime safety requirements for vessels restricted in their ability to maneuver (RAM), including enforcement of the 500 m safety zone. | Compatible with offshore drilling unit operations, aviation support activities, and safe navigation across all anticipated weather conditions.                                                        | Standard industry configuration with no additional equipment or operational cost implications.                                                         | Results in localised light emissions and potential visual disturbance; impacts are managed within standard regulatory-compliant operational controls, with no feasible reduction available given the safety function of the lighting. | <b>Preferred alternative.</b><br>Required to maintain safe offshore operations, navigation, and aviation activity while ensuring full regulatory compliance.                                  |
| <b>Spectral-Modified or Alternative Lighting Systems</b>                | Not accepted as a substitute for mandatory marine navigation lighting requirements; any use would be supplementary at most, not a replacement for COLREGS/SOLAS-mandated lighting.          | Reduced reliability in poor weather conditions and for aviation operations, including helicopter approach and landing, compared with standard lighting.                                               | Would require additional equipment and testing without replacing mandatory lighting, representing added cost with no corresponding regulatory benefit. | Any visual impact reduction is not achievable in practice, since mandatory lighting levels cannot be lowered for RAM vessel and safety-zone compliance.                                                                               | <b>Not preferred.</b><br>Not feasible as a substitute for standard lighting. Cannot meet mandatory safety and operational requirements for offshore drilling units classified as RAM vessels. |
| <b>Reduced or Intermittent Lighting (including No Lighting Periods)</b> | Not compliant with COLREGS, SOLAS, or Greek maritime safety requirements for vessels restricted in their ability to manoeuvre and operating within an enforced safety zone.                 | Continuous lighting is required to ensure vessel visibility, collision avoidance, and safe coordination of marine and aviation operations; intermittent or no-lighting periods would compromise this. | Not applicable, as the option is excluded on legal and safety grounds before cost considerations arise.                                                | Not applicable, as the option cannot be implemented.                                                                                                                                                                                  | <b>Not preferred.</b><br>Excluded outright. Fails fundamental safety, legal, and navigational requirements; not a viable alternative under any operational scenario.                          |

## 7.2.10 Well Decommissioning

Asopus 1 is designed, permitted, and assessed as an exploration well only. Following completion of drilling and formation evaluation, the well will be plugged and abandoned (P&A) in accordance with applicable Greek legislation, HEREMA requirements, and good international industry practice. The P&A programme includes the installation and verification of permanent well barriers to ensure long term well integrity and environmental protection.

In line with industry practices for deepwater drilling, the wellhead will be left in place. Retention of the wellhead does not alter the abandonment status of the well. The well will be rendered non flowing and environmentally secure, with no connection to the reservoir and long-term leakage risk is minimised through installation and verification of permanent well barriers in accordance with applicable standards and regulatory requirements. All temporary subsea infrastructure (including the BOP, marine riser, and transponders) will be removed, and no production facilities, pipelines, control umbilicals, or surface installations will be installed.

The physical seabed footprint of a retained wellhead is small (less than 1 m<sup>2</sup>) and does not require routine inspection, operations, or physical intervention activities. The well location is in approximately 840 m water depth, which is significantly deeper than the operating depth of commercial fishing activities in the Ionian Sea. As a result, retention of the wellhead is not expected to disturb fishing activity or restrict access to fishing grounds or other marine users.

From an environmental perspective, retaining the wellhead avoids additional seabed disturbance and vessel activity that would otherwise be required for immediate removal followed by potential future re-entry, and is therefore considered a proportionate and precautionary measure. Retention of the wellhead does not constitute approval of appraisal, development, or production activities. Any future proposal to re-enter the well, drill appraisal wells, conduct well testing, install subsea or surface facilities, or modify the well status would be subject to separate regulatory submissions, environmental and social impact assessments, public consultation, and approval by the competent authorities.

Records of the final P&A configuration, installed barriers, and wellhead status will be prepared and submitted to the relevant authorities to ensure a transparent and auditable regulatory record. The final abandonment configuration, including any retained subsea equipment, will be subject to approval through the applicable regulatory processes and will be implemented in accordance with applicable Greek legislation, HEREMA requirements and relevant obligations of the Barcelona Convention Offshore Protocol.

**Table 7-9: Well Decommissioning Alternative Analysis**

| OPTION                         | REGULATORY COMPATIBILITY                                                                                                                                                                                   | TECHNICAL FEASIBILITY                                                                                                                            | FINANCIAL FEASIBILITY                                                                                        | ENVIRONMENTAL COMPATIBILITY                                                                                                                                            | OVERALL ASSESSMENT                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Leave wellhead in place</b> | Consistent with Greek offshore safety legislation, which requires permanent well sealing but does not prescribe wellhead removal as a specific requirement. The approach is part of the NoWO, in line with | Technically straightforward: the well is fully plugged and abandoned with verified permanent barriers, requiring no further subsea intervention. | Avoids the additional subsea intervention and drillship time associated with full removal, reducing offshore | Minimises additional seabed disturbance and vessel activity; the retained structure has a very small footprint (<1 m <sup>2</sup> ) and no operational requirement. No | <b>Preferred alternative.</b> Provides a proportionate, precautionary approach that ensures long-term well integrity while minimising unnecessary |

| OPTION                                                        | REGULATORY COMPATIBILITY                                                                                                                                                                                                                               | TECHNICAL FEASIBILITY                                                                                                                                                     | FINANCIAL FEASIBILITY                                                                                                      | ENVIRONMENTAL COMPATIBILITY                                                                                                                                                                                                               | OVERALL ASSESSMENT                                                                                                                                                                                  |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                               | established international practice for deepwater well abandonment.                                                                                                                                                                                     |                                                                                                                                                                           | operational cost.                                                                                                          | interaction with fisheries is expected given the water depth (~840 m).                                                                                                                                                                    | environmental disturbance.                                                                                                                                                                          |
| <b>Full Wellhead Removal (Immediate Removal in All Cases)</b> | Also consistent with the same Greek legislative framework, which does not distinguish between removal and retention as a compliance requirement; this option would similarly be presented to HEREMA through the well abandonment notification process. | Requires additional subsea intervention, including cutting and lifting operations, in all scenarios regardless of whether retention would be equally or more appropriate. | Increased offshore drillship time, subsea operations, and associated logistics raise overall cost compared with retention. | Results in additional seabed disturbance and increased vessel activity without a corresponding environmental benefit, particularly where future re-entry potential may need to be preserved; no impact to other marine users is expected. | <b>Not preferred.</b><br>Technically feasible but introduces additional seabed disturbance, emissions, and operational effort without a clear environmental or regulatory advantage over retention. |

## 7.2.11 Management of Operations and Support Infrastructure

The logistics setup for the Asopus 1 exploration drilling programme includes an onshore supply base to support marine logistics and a helicopter base to support personnel transfer and emergency response. During early project planning, Energean undertook a broad screening of logistics options using its regional offshore experience and engagement with potential service providers.

The assessment considered only existing ports and aviation facilities and applied the following criteria:

- Technical suitability for offshore drilling logistics;
- Distance to the offshore operational area;
- Ability to support short term exploration activity;
- Safety and environmental footprint; and
- Commercial interest and availability.

Several options were reviewed but were determined to be impractical, unsuitable, or unavailable for this Project and were therefore screened out prior to detailed assessment.

### 7.2.11.1 Shore base

A structured alternatives assessment was undertaken to identify a suitable shore base for the Asopus-1 offshore exploration drilling programme. The assessment was undertaken at a screening level appropriate to the temporary nature of the Project and considered the use of existing port infrastructure only, as no new shore base construction is proposed.

Ports considered included Igoumenitsa, Patras and Thisvi, together with other western Greek ports that were screened out at an early stage due to technical constraints, including insufficient draft, or because they were too distant from the offshore well location. The assessment considered proximity to the well, vessel transit

time, availability of suitable berth and laydown space, operational compatibility with offshore logistics, and the potential to minimise fuel use, emissions and operational delay.

Following screening, Igoumenitsa was identified as the preferred shore base. It provides the shortest practical sailing distance to the offshore location among the suitable existing options considered and offers compatible existing infrastructure for temporary offshore logistics support without the need for new port infrastructure. Patras and Thisvi were both considered feasible in principle but were less favourable overall due to a combination of greater distance and lower logistics efficiency for the Project. In the case of Thisvi, bidder availability was also not secured, as the bidder ultimately decided not to submit a bid.

On this basis, Igoumenitsa was identified as the preferred shore base option for the Asopus-1 Project, taking account of technical suitability, operational efficiency, commercial availability and environmental considerations.

**Table 7-10: Shore base Location Alternative Analysis**

| OPTION                                                  | REGULATORY COMPATIBILITY                                                                                                                                  | TECHNICAL FEASIBILITY                                                                                                                                                  | FINANCIAL FEASIBILITY                                                                                                                                  | ENVIRONMENTAL COMPATIBILITY                                                                                                                                     | OVERALL ASSESSMENT                                                                                                                                              |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Igoumenitsa – Shore Base</b>                         | Compliant with applicable port, maritime, and offshore logistics regulations, with existing infrastructure requiring no new permitting for temporary use. | Existing port infrastructure supports temporary offshore drilling logistics, including vessel berthing, cargo handling, and laydown requirements without modification. | Shortest transit time to the offshore location among the options considered, reducing vessel time and associated logistics costs.                      | Shortest practical sailing distance among suitable options, resulting in reduced fuel consumption, vessel emissions, and overall logistical footprint.          | <b>Preferred alternative.</b><br>Offers the optimal balance of proximity, infrastructure suitability, operational efficiency, and reduced environmental impact. |
| <b>Patras – Shore Base (Alternative Option)</b>         | Compliant with applicable regulations on the same basis as Igoumenitsa.                                                                                   | Existing port infrastructure can support offshore logistics operations for exploration activities, comparable to Igoumenitsa in capability.                            | Longer transit distance to the offshore location increases vessel time and associated logistics costs relative to Igoumenitsa.                         | Increased vessel transit distances result in higher fuel consumption, emissions, and underwater noise compared with Igoumenitsa.                                | <b>Not preferred.</b><br>Technically viable but less efficient due to greater distance and increased environmental footprint relative to Igoumenitsa.           |
| <b>Thisvi – Shore Base (Screened Alternative)</b>       | Compliance would depend on confirmation of port access and commercial arrangements, which were not secured for this Project.                              | Suitable infrastructure exists in principle, but bidder interest and confirmed operational availability were not secured.                                              | Lack of confirmed commercial participation removes this option as a reliable logistics solution, independent of underlying infrastructure suitability. | Longer transit distances than Igoumenitsa would result in a less efficient environmental performance, though this was not the determining factor for exclusion. | <b>Not preferred.</b><br>Screened out primarily due to lack of secured commercial/bidder availability, not due to a technical or regulatory deficiency.         |
| <b>Other Western Greek Ports (Screened Out Options)</b> | Compliance status varies by port and was not assessed in detail, as these options were                                                                    | Excluded due to insufficient draft, limited infrastructure, or excessive distance from                                                                                 | Not assessed in detail, as these ports were excluded on technical grounds before                                                                       | Not assessed in detail; longer sailing distances would generally result in higher emissions, but                                                                | <b>Not preferred.</b><br>Screened out. Excluded at an early stage due to technical constraints (draft, infrastructure,                                          |

| OPTION | REGULATORY COMPATIBILITY                                   | TECHNICAL FEASIBILITY                                  | FINANCIAL FEASIBILITY                | ENVIRONMENTAL COMPATIBILITY           | OVERALL ASSESSMENT                                                  |
|--------|------------------------------------------------------------|--------------------------------------------------------|--------------------------------------|---------------------------------------|---------------------------------------------------------------------|
|        | excluded at the screening stage before further evaluation. | the offshore location, depending on the specific port. | financial feasibility was evaluated. | this was not the basis for exclusion. | distance), prior to detailed financial or environmental assessment. |

### 7.2.11.2 Heliport

A range of existing aviation facilities in western Greece was screened as potential helicopter bases to support personnel transfers and emergency response for the Asopus-1 exploration drilling programme. The screening considered only certified facilities and focused on operational experience in safely supporting helicopter operations, proximity to the offshore site, available infrastructure and capacity during the planned drilling window, and compatibility with a short-duration offshore exploration campaign.

Several facilities were excluded at an early stage due to limited aviation infrastructure, lack of experience with offshore helicopter operations, or operational constraints. Corfu International Airport (CFU) was identified as the most suitable option due to its established experience in safely supporting helicopter operations, relatively short distance to the well location, and sufficient installed capacity outside the peak tourism season. The reduced flight distance and use of existing infrastructure minimise helicopter flight time, fuel consumption, and associated environmental impacts.

**Table 7-11: Heliport Location Alternative Analysis**

| OPTION                                                  | REGULATORY COMPATIBILITY                                                                                                                                    | TECHNICAL FEASIBILITY                                                                                                         | FINANCIAL FEASIBILITY                                                                                                                 | ENVIRONMENTAL COMPATIBILITY                                                                                                                          | OVERALL ASSESSMENT                                                                                                                                                               |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Corfu International Airport (Helicopter Base)</b>    | Compliant with civil aviation and offshore helicopter operational requirements, with no additional certification or infrastructure required.                | Certified airport with established operational experience supporting offshore helicopter operations.                          | Adequate capacity and infrastructure are available during the planned drilling period, requiring no additional investment or upgrade. | Shorter flight distances to the offshore location reduce fuel consumption, emissions, and airborne noise impacts relative to alternative facilities. | <b>Preferred alternative.</b> Provides the most efficient and operationally suitable aviation support solution for the Project.                                                  |
| <b>Alternative Regional Airports (Screened Options)</b> | Compliance would depend on certification status of the specific facility, which was not confirmed for offshore helicopter operations in the cases reviewed. | Several facilities lacked sufficient offshore helicopter operational experience or confirmed capacity to support the Project. | Not assessed in detail, as these options were excluded on technical/operational grounds before financial feasibility was evaluated.   | Not assessed in detail; greater distances would generally increase flight time, emissions, and noise, but this was not the basis for exclusion.      | <b>Not preferred.</b> Excluded at an early stage due to limited offshore helicopter operational experience or capacity, prior to detailed financial or environmental assessment. |

### 7.2.11.3 Support Vessels

Support vessel requirements for the Asopus-1 exploration drilling programme were evaluated to ensure operational efficiency and safety while minimising marine traffic, fuel consumption and environmental disturbance. Given the short duration of the drilling campaign, the limited logistics demands of a single exploration well, and the proximity of the selected shore base at Igoumenitsa, a reduced support vessel configuration was selected.

The Project will utilise two platform supply vessels (PSVs), instead of the three-vessel configuration typically used in other offshore drilling campaigns. This approach provides an appropriate balance between operational safety and environmental performance, based on Energean's assessment of the well-specific logistics demand for a single exploration well with a drillship. One vessel will typically remain in the vicinity of the drilling unit, while the second will undertake logistics transits between the drilling location and the shore base.

The selected configuration is supported by the capabilities of modern drillships, which have significant onboard storage capacity and advanced logistics management systems, reducing the need for additional dedicated supply vessels. The use of two vessels, combined with shorter sailing distances to Igoumenitsa, reduces overall vessel movements, fuel consumption, atmospheric emissions and underwater noise compared with a three-vessel configuration.

This reduced vessel approach is considered technically feasible, operationally appropriate and consistent with minimisation-by-design principles for a short-duration offshore exploration well.

**Table 7-12: Support Vessels Alternative Analysis**

| OPTION                                                      | REGULATORY COMPATIBILITY                                                                    | TECHNICAL FEASIBILITY                                                           | FINANCIAL FEASIBILITY                                                                                     | ENVIRONMENTAL COMPATIBILITY                                                                                             | OVERALL ASSESSMENT                                                                                                                        |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>2-PSV Configuration</b>                                  | Fully compliant with applicable maritime regulations and offshore operational requirements. | Supported by modern drillship storage capacity and efficient logistics systems. | Optimised configuration reduces vessel hire and operating costs while maintaining operational continuity. | Reduced vessel movements, fuel consumption, emissions, and underwater noise compared with a three-vessel configuration. | <b>Preferred alternative.</b><br>Achieves a balanced, minimised logistics footprint while maintaining operational safety and efficiency.  |
| <b>3-PSV Configuration (Higher Vessel Intensity Option)</b> | Fully compliant with applicable maritime safety and operational regulations.                | Standard configuration used in comparable offshore drilling campaigns.          | Higher vessel charter and operating costs due to increased fleet size and logistics complexity.           | Increased vessel traffic results in higher fuel consumption, emissions, and underwater noise.                           | <b>Not preferred.</b><br>Technically viable but less efficient in terms of emissions and logistics for a short-duration exploration well. |

## 7.3 Evaluation of Alternatives

A structured alternatives assessment was undertaken for the Asopus-1 exploration drilling programme to identify the most appropriate options for achieving the Project objectives while minimising environmental impacts and operational risks.

The assessment considered reasonable alternatives for key elements of the Project, including the well location, well trajectory, drilling unit type, drilling strategy, drilling fluids, cuttings management, cementing approach, lighting, abandonment strategy, and supporting logistics infrastructure.

Each alternative was evaluated against four criteria:

- Regulatory compatibility – consistency with applicable legislation, permit requirements, and recognised industry standards;
- Technical feasibility – suitability of the option to safely achieve the Project objectives under the anticipated site conditions;
- Financial feasibility – relative cost and operational efficiency of the option;
- Environmental compatibility – potential to avoid or minimise environmental disturbance, emissions, waste generation, and resource use.

For each criterion, alternatives are assessed qualitatively using the following rating system:

**Table 7-13: Alternatives Assessment Rating System**

| ASSESSMENT CRITERIA                                                       | RATING OPTIONS               | DESCRIPTION                                                                                                                                                                  |
|---------------------------------------------------------------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Regulatory compatibility                                                  | Compliant                    | Meets applicable legislation, permit requirements, and recognised industry standards without qualification.                                                                  |
|                                                                           | Conditionally compliant      | Compliance is achievable in principle but subject to permit conditions, competent authority approval, or infrastructure/site-specific requirements not met at this location. |
|                                                                           | Not compliant / Not feasible | Cannot meet applicable legislation or permit requirements; excluded on regulatory grounds.                                                                                   |
| Technical feasibility, financial feasibility, Environmental compatibility | Favourable                   | Fully suitable, with no significant limitations identified.                                                                                                                  |
|                                                                           | Acceptable with limitations  | Suitable in principle, but with identified limitations, disadvantages, or reduced efficiency relative to the favourable option.                                              |
|                                                                           | Unfavourable                 | Presents significant limitations, increased impacts, or reduced effectiveness.                                                                                               |
|                                                                           | Not feasible                 | Unable to meet technical, financial, or environmental requirements; excluded from further consideration.                                                                     |
| Overall assessment                                                        | Preferred                    | Represents the most appropriate balance across all criteria; selected option.                                                                                                |
|                                                                           | Not preferred                | Viable in principle but presents a less favourable balance than the preferred option.                                                                                        |
|                                                                           | Not feasible                 | Excluded outright on regulatory, technical, or operational grounds.                                                                                                          |

The assessment was undertaken using engineering information, technical data, environmental considerations, operational requirements, and industry experience. Where alternatives were found to be technically or regulatorily infeasible, they were screened out and not considered further.

The preferred option for each Project component was selected on the basis that it represented the most appropriate balance between technical performance, environmental protection, operational efficiency, and regulatory compliance.

Table 7-14 summarises the assessment for all topic areas (well location, trajectory, MODU, drilling strategy, fluids, cementing, lighting, abandonment, logistics, etc.).

**Table 7-14: Summary of Alternative Assessment for the Asopus-1 exploration well**

| AREA              | OPTION                                          | REGULATORY                   | TECHNICAL                   | FINANCIAL                   | ENVIRONMENT                 | OVERALL                                                                                                                                                   |
|-------------------|-------------------------------------------------|------------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

## 7.4 Conclusion

The alternatives assessment for the Asopus-1 exploration well was undertaken during the early stages of project design, when design and logistics choices could still influence environmental performance, safety, technical feasibility and operational efficiency. A range of reasonable alternatives was considered and evaluated against common criteria, including regulatory compatibility, technical feasibility, environmental performance, logistics efficiency and proportionality to the limited scope and duration of a single offshore exploration well.

The assessment identified a **preferred project configuration** comprising:

- selection of the most geologically favourable **well location** (1A).
- use of a simple **vertical** or low-inclination well trajectory.
- deployment of a **drillship** suitable for deepwater conditions.
- execution of a **single drilling campaign** to minimise mobilisation and emissions.
- use of **water-based drilling fluids** with discharge of cuttings to sea under permit conditions.
- Conventional oilfield **cement systems** to ensure robust long-term well integrity.
- standard regulatory-compliant **lighting** required for navigation and aviation safety.
- a proportionate **abandonment strategy** including retention of the wellhead following P&A.
- selection of the closest suitable **shore base (Igoumenitsa)** and established helicopter base (Corfu International Airport).
- optimisation of logistics through a reduced configuration of **two PSVs**.

The selected configuration makes use of existing infrastructure and established offshore drilling practices while reducing the duration and extent of offshore activities. It avoids seabed disturbance associated with anchoring, limits vessel and aviation movements with the closest suitable logistics facilities, avoids emissions associated with well testing and flaring, and minimises operational complexity consistent with the objectives of a single exploration well.

Alternatives not selected were generally associated with increased environmental disturbance, greater logistics requirements, higher operational risk, or additional technical complexity without delivering a corresponding environmental or operational benefit. In several cases, options that may be appropriate for appraisal or development projects were considered disproportionate for a short-duration exploration programme. Other alternatives were screened out because they were not technically feasible or could not meet applicable regulatory requirements.

The No-Action Alternative was also considered. Although this option would avoid project-related environmental and social effects, it would not meet the exploration objectives of the Project, would prevent acquisition of the geological and reservoir information sought through the well, and would not fulfil the minimum work obligations associated with the Block 2 Lease Agreement.

On this basis, the selected Project configuration is considered to represent the preferred option for the Asopus-1 exploration drilling programme. It provides an appropriate balance between environmental protection, safety, technical feasibility, regulatory compliance and operational efficiency, consistent with good international industry practice for offshore exploration activities.

## 8 Baseline environmental conditions

Section 8 presents a summary of the findings of the 2nd stage Environmental and Social Baseline Study (ESBS) undertaken for the Project. The information presented herein is derived primarily from the ESBS, which is included as Annex 02 of this ESIA together with its accompanying specialist technical studies. This section summarizes the baseline conditions relevant to the environmental and social impact assessment, whereas the full ESBS (Annex 02) provides the complete baseline characterization, including detailed methodologies, datasets, analyses, results, and supporting technical information.

The preparation of the ESBS is a mandatory requirement under the Greek legislative framework, specifically Article 12.14 of the Lease Agreement, which was subsequently ratified by Law 4525/2018, which requires the documentation of baseline environmental conditions prior to the commencement of offshore activities. The baseline establishes the reference conditions against which potential future environmental changes attributable to the Project can be assessed. In addition, it fulfils the baseline requirements established under the Strategic Environmental Assessment (SEA) Approval for the Ionian Sea (Approval No. 30373/03.07.2017).

The 2nd stage ESBS was prepared by the Environmental Consultant (LDK Consultants S.A. and RSK International Projects Group) and integrates both secondary and primary environmental data to characterize the wider Block 2 concession area and the immediate Project area.

Secondary information comprises an extensive review of published scientific literature and official environmental databases, including the European Marine Observation and Data Network (EMODnet), the Water Information System for Europe (WISE), the European Atlas of the Seas, and the IUCN Red List, together with information compiled during the 1st stage ESBS for the Block 2 concession area (prepared by RINA in 2018), which provided the initial characterization of the wider concession area.

Primary data were collected through two dedicated offshore survey campaigns (LOT 01 – Geophysical Survey and LOT 02 – Environmental Survey) undertaken from the survey vessel M/V ECO ONE. Lighthouse SpA was appointed by Energean to execute the offshore surveys, supported by EcoTechSystems Srl for environmental sampling and laboratory analyses, and Bluemetoccean Srl for oceanographic current measurements and underwater acoustic analyses.

The LOT 01 Geophysical Survey was conducted between 5 and 27 April 2026 over an area of approximately 100.2 km<sup>2</sup>. The objectives of the survey were to characterize seabed morphology, identify potential geohazards, and investigate underwater cultural heritage. The survey primarily employed a Kongsberg HUGIN 4500+ Autonomous Underwater Vehicle (AUV) equipped with a Multibeam Echosounder (MBES), High-resolution Interferometric Synthetic Aperture Sonar (HISAS), Sub-Bottom Profiler (SBP), and magnetometer. High-altitude AUV missions were undertaken for acoustic seabed mapping, while low-altitude missions employed ultra-high-definition optical cameras (Cathx) to verify benthic biocenoses and investigate selected archaeological targets. The campaign also included the deployment of a moored Acoustic Doppler Current Profiler (ADCP) with single-point current meters to characterize oceanographic current dynamics, together with a Passive Acoustic Monitoring (PAM) system comprising a broadband hydrophone and an RTSYS Sylence-LP autonomous recorder to establish the underwater acoustic baseline.

The LOT 02 Environmental Survey was undertaken between 14–17 March and 23 March–1 April 2026 to characterize the physical, chemical, and biological conditions of the marine environment. Sampling was

conducted at 16 stations, including stations surrounding the proposed well location, northern stations, blank stations, and three regional reference stations (Othonoi Ref, Kerkyra Ref, and Italy Ref).

Water-column investigations included profiling with a CTD multiparameter probe to measure conductivity, temperature, pressure, pH, dissolved oxygen, turbidity, and fluorescence. Water samples were collected at surface, mid-water, and near-bottom depths for the analysis of total suspended solids, total organic carbon, nutrients, trace metals, hydrocarbons, and phytoplankton communities. Environmental DNA (eDNA) samples were collected exclusively from near-bottom waters. Zooplankton communities were sampled using vertical net tows through the upper 200 m of the water column, while ichthyoplankton (fish larvae) was sampled using oblique net tows along three dedicated 1 km transects.

Sediment samples were collected at all stations using a Van Veen grab for physicochemical characterization, including grain-size distribution, organic matter, trace metals, hydrocarbons, microplastics, and macrozoobenthic community assessments. High-resolution AUV imagery acquired during the geophysical survey was also incorporated into the environmental baseline to support the characterization of benthic habitats and assess the spatial distribution of seafloor marine litter.

Dedicated marine fauna monitoring was undertaken throughout both survey campaigns. Daytime visual observations were conducted by Marine Mammal Observers (MMOs) and avifauna specialists to record cetaceans, sea turtles, and seabirds, including species identification and behavioural observations. Night-time monitoring was undertaken using the Passive Acoustic Monitoring (PAM) system.

The phase 2 ESBS (provided as Annex 02 of the ESIA) is supported by a suite of specialist technical reports, including the List of marine fish fauna species (ESBS Annex 01), Geophysical Survey Report (ESBS Annex 02), Report on possible ruins of an ancient shipwreck (ESBS Annex 03A), Archaeological Baseline Assessment Report (ESBS Annex 03B), Current Meter Data Analysis Report (ESBS Annex 04), Acoustic Data Analysis Report (ESBS Annex 05), and Environmental Baseline Survey Report (ESBS Annex 06). Additionally, the eDNA study is provided as a stand-alone document in Annex 03 of the ESIA.

## 8.1 Study area

In accordance with Annex II of Ministerial Decision (MD) 170225/2014 (Government Gazette 135/B/20.01.2014), which specifies the content of environmental licensing documentation for Category A projects pursuant to Article 11 of Law 4014/2011, the minimum study area for point projects classified under Subcategory A1 and located outside settlement boundaries, as is the case for the Asopus-1 exploration well, extends to a radius of 2 km from the project boundaries. However, as explicitly stated in the MD, this distance represents the minimum regulatory extent of the study area and should not be interpreted as the maximum area potentially affected by the Project. Accordingly, the spatial extent of the baseline characterization presented in the 2nd Stage ESBS was established on a receptor-specific basis, taking into account the nature and scale of the Project, the sensitivity and characteristics of the environmental and social receptors, and the anticipated spatial extent of potential direct, indirect, cumulative, and transboundary effects. Consequently, the spatial coverage of the baseline information varies according to the environmental and social topic under consideration. The study area for the field surveys was extended to a 10 km radius from the Project boundaries, providing an appropriate framework for the collection and assessment of baseline environmental data. For mobile biotic receptors, a 20 km radius was adopted due to the greater mobility of these species.

With regard to the Project's shorebase facilities, these will be located at the existing Port of Igoumenitsa. In accordance with Annex II of Ministerial Decision 170225/2014, the study area was defined as a minimum distance of 1 km from the boundaries of point and area projects or activities classified under Subcategory A2 and located outside settlement boundaries or approved urban plans.

For the assessment of the socio-economic environment, a broader study area was adopted to reflect the administrative areas associated with the Project and its shorebase facilities. At the administrative level, the Regional Unit of Corfu represents the closest onshore administrative area to the Asopus-1 exploration well and Block 2 and forms part of the Ionian Islands Region. Furthermore, the Municipality of Igoumenitsa constitutes the principal onshore administrative area currently planned to be associated with the Project's maritime logistics activities, as the Port of Igoumenitsa is expected to serve as the operational base for Platform Supply Vessel (PSV) movements supporting the offshore drilling operations.

## 8.2 Climate and bioclimatic characteristics

### 8.2.1 Climatic characteristics

The climate of the broader Northern Ionian Sea, including the Asopus-1 exploration well area, is classified as a Mediterranean hot-summer climate according to the Koppen-Geiger climate classification for the period 1985–2014 (Lionello et al., 2023, Gutiérrez et al., 2021). The regional climate is influenced by large-scale atmospheric circulation systems, including the Azores Anticyclone, the Siberian Winter Anticyclone, the Icelandic Low, and the South Asian Thermal Low.

The annual climatic cycle is characterised by two principal seasons separated by transitional periods. During winter (mid-November to March), the region is influenced by the passage of cyclonic systems and associated low-pressure conditions, resulting in relatively low temperatures, increased cloud cover, higher precipitation, and predominantly northeasterly winds. In contrast, summer (June to September) is generally characterised by stable atmospheric conditions, clear skies, limited precipitation, and the development of local sea- and land-breeze circulations associated with land-sea temperature differences. The transitional periods, particularly autumn, are associated with increased rainfall resulting from interactions between relatively warm sea surface temperatures and cooler continental air masses.

Long-term climatological data from the Hellenic National Meteorological Service (1971–2000) for the island of Othonoi indicate mean monthly temperatures ranging from 8.3 °C in January to 25.0 °C in July, while mean monthly precipitation ranges from 8.3 mm in July to 178.6 mm in November. Meteorological data from the National Observatory of Athens (2010–2019) for Igoumenitsa, the nearest mainland meteorological station to the Project area, indicate average monthly temperatures ranging from 8.6 °C in January to 26.9 °C in August, with monthly precipitation varying from 10 mm in July and August to 230 mm in November.

A 10-year MET-OCEAN hindcast study (1 January 2015 to 31 December 2024) undertaken by SAT-OCEAN indicates that winds at the Asopus-1 location predominantly originate from the north-northwest (NNW), with typical wind speeds between 5 and 10 m/s. Between October and March, the frequency of wind speeds exceeding 15 m/s increases, particularly during January and February, with these stronger winds occurring predominantly from the NNW, north (N), and south-southeast (SSE).

Meteorological observations collected during the offshore survey campaigns were generally consistent with these regional conditions. During LOT 01, comprising 373 hours of acoustic and visual observations, horizontal visibility exceeded 5 km throughout the survey period, while no precipitation was recorded. Prevailing winds originated from the north and northwest, with wind conditions most frequently corresponding to Beaufort Force 4 (approximately 30%) and Beaufort Force 3 (approximately 27%).

During LOT 02, 115 hours of visual observations were undertaken. Horizontal visibility exceeded 5 km for 96% of the survey period. No precipitation was recorded during 87.1% of the observations, while light rain and moderate rain occurred during 11.1% and 1.5% of the observations, respectively. Prevailing winds originated from the northwest (29%), southwest (14%), and north (10%), with wind conditions most frequently corresponding to Beaufort Force 4 (45%), Beaufort Force 5 (24%), and Beaufort Force 3 (14%). Sea conditions were predominantly classified as choppy, while swell height was generally low (<2 m).

## 8.2.2 Oceanographic characteristics

The Mediterranean Sea is a concentration basin, where evaporation exceeds the combined inputs from precipitation and river runoff. This hydrological imbalance drives an anti-estuarine circulation, whereby relatively low-salinity Atlantic waters enter the Mediterranean, become warmer and more saline as they circulate eastwards, and subsequently contribute to the formation of denser water masses that are exported towards the western Mediterranean (Coll et al., 2010; Otero & Mytilineou, 2022).

The principal water masses in the Ionian Sea comprise Modified Atlantic Water in the surface layer, Levantine Intermediate Water between approximately 150 and 500 m depth, and Eastern Mediterranean Deep Water below approximately 1,600 m (Schlitzer et al., 1991; Malanotte-Rizzoli et al., 1997). Ocean circulation in the northern Ionian Sea is also influenced by quasi-decadal reversals of the North Ionian Gyre, which affect the thermohaline characteristics of the basin (Borzelli et al., 2009; Gacic et al., 2010; Bensi et al., 2016). Below approximately 300–500 m, the water column is generally characterized by relatively uniform temperatures ranging from 13.5 °C to 15.5 °C and salinity between 37.5 and 39.5 PSU (Coll et al., 2010).

A 10-year MET-OCEAN hindcast study (1 January 2015 to 31 December 2024) undertaken by SAT-OCEAN indicates seasonal variability in surface circulation at the Asopus-1 location. Surface currents predominantly flow towards the north to north-northeast between October and May, shifting towards the east-southeast to southeast during June to September. In contrast, deeper currents show limited seasonal variability. Below approximately 300 m, currents generally flow towards the northwest at velocities below 0.2 m/s, while below approximately 800 m, they are predominantly directed towards the north-northeast with velocities generally below 1 m/s.

Current measurements were collected from a mooring equipped with single-point current meters, deployed between 5 and 27 April 2026 (LOT01) at a location approximately midway between Corfu and Italy (coordinates: 333412.13 mE, 4374226.35 mN, WGS84-UTM34N). Near-seabed measurements indicated stable current conditions, with velocities generally below 0.10 m/s and a predominant south-southeasterly flow.

During LOT 02, continuous conductivity, temperature and depth profiling was undertaken to characterize the thermohaline structure of the water column. A vertically homogeneous surface layer extended to approximately 95 m depth, with temperatures between 16 and 17 °C and salinity below 38.8 PSU, consistent

with the presence of Modified Atlantic Water. Between approximately 100 and 250 m, a marked thermohaline transition was observed, with salinity reaching or exceeding 39.1 PSU, indicating the presence of Levantine Intermediate Water (Malanotte-Rizzoli et al., 1997, 1999; Menna et al., 2021; Fedele et al., 2022; Mallil et al., 2022). At the planned drilling depth of the Asopus-1 well (842.5 m), the water column exhibited typical Eastern Mediterranean deep-water conditions, with a temperature of approximately 13.8 °C, salinity of 38.8 PSU, and dissolved oxygen concentrations of approximately 4.2 mL/L.

### 8.2.3 Bioclimatic Characteristics

The Northern Ionian Sea is characterised by oligotrophic conditions, with low nutrient availability and limited primary productivity, which are typical features of the Mediterranean marine environment (Otero & Mytilineou, 2019).

Data collected during the LOT 02 Environmental Survey Campaign (14–17 March and 23 March–1 April 2026) were consistent with these regional characteristics. Nutrient analyses showed that Total Nitrogen concentrations were below the analytical limit of quantification (LoQ = 1 mg/L) throughout the water column, while nitrite (LoQ = 0.002 mg/L N) and nitrate (LoQ = 0.005 mg/L N) concentrations were also below quantification limits around the Asopus-1 well location. Total Organic Carbon concentrations in surface sediments were low ( $0.10 \pm 0.07\%$  dry weight), and phytoplankton biomass, expressed as chlorophyll-a, reached a maximum of 0.33 µg/L, indicating low primary productivity within the Project area (Barbieux et al., 2019).

### 8.2.4 Climate Change – Extreme Weather Events

The Mediterranean basin is experiencing warming at a rate approximately 20% higher than the global average (Lionello & Scarascia, 2018). Regional climate projections based on EURO-CORDEX downscaled models indicate an increase in the frequency of days with maximum temperatures exceeding 40 °C under both 2 °C and 4 °C global warming scenarios (Gutiérrez et al., 2021). Sea surface temperatures in the Mediterranean have shown an increasing trend since the 1970s, contributing to changes in the distribution of sea surface temperature patterns and facilitating the expansion of warm-water non-indigenous species within the basin (Zenetos et al., 2022). Climate projections also indicate continued sea-level rise throughout the 21st century under different emission scenarios, including RCP4.5 and RCP8.5, with potential implications for coastal areas, including increased coastal erosion risks (Kopp et al., 2014; Marcos et al., 2023).

For the northern Ionian Sea, including the Asopus-1 well area, regional climate projections indicate changes in temperature and hydrological conditions associated with future warming. Increased atmospheric temperatures are expected to result in higher atmospheric moisture content in accordance with the Clausius–Clapeyron relationship (Lionello & Scarascia, 2020). While climate models project an overall reduction in annual precipitation across much of the Mediterranean basin (approximately 4% per degree Celsius of warming; Lionello & Scarascia, 2018), the northern Mediterranean sub-region, including the wider Project area, presents different model responses, with projections indicating potential increases in extreme precipitation events (Lionello & Scarascia, 2020).

Within the marine environment, projected increases in seawater temperature are expected to occur alongside ongoing ocean acidification associated with increased atmospheric CO<sub>2</sub> concentrations (Otero & Mytilineou, 2019). These changes may affect marine ecosystems through alterations in biological processes, including calcification rates in marine organisms, with potential implications for planktonic communities and other sensitive marine habitats (Otero & Mytilineou, 2019).

Regarding extreme oceanographic events, tsunamis in the Mediterranean are primarily associated with seismotectonic processes, including activity along the Hellenic Arc, regional tectonic movements, and submarine slope instability. Historical records indicate that the wider Ionian Sea and Hellenic Shelf have been affected by tsunami events and weather-related meteotsunamis, with palaeo-tsunami evidence identified along the coastlines of Corfu. Based on regional seismotectonic characteristics and the currently available geophysical information, the likelihood of a tsunami originating directly from the Asopus-1 well location is considered low, given its distance from the main active subduction zones of the Hellenic Arc and the absence of identified local conditions typically associated with major submarine slope failure mechanisms.

## 8.3 Morphological And Topographical Characteristics

### 8.3.1 Bathymetry

The Asopus-1 exploration well is located in the northern part of the Ionian Sea. The Ionian Sea constitutes a major marine region of the Eastern Mediterranean and represents the deepest marine basin within the Mediterranean. The basin is characterized by extensive submarine canyon systems, with depths exceeding 4,000 m and a maximum recorded depth of over 5,100 m at the Vavilov Deep, located approximately 30 miles southwest of the Peloponnese (Sammartino et al., 2022).

In the northern Ionian Sea, regional bathymetry varies considerably. From the continental shelf adjacent to the Diapontia Islands, the seabed descends along a submarine slope towards the central-eastern sector, reaching depths of approximately 1,200 m along the margin of Corfu. The Block 2 concession area is located southwest of the base of this regional slope, at water depths generally ranging between 750 and 1,200 m. Within the concession area, the seabed forms a relatively gentle and gradually rising profile towards the Italian continental slope over a distance of approximately 100 km.

Detailed bathymetric mapping undertaken during the LOT 01 Geophysical Survey Campaign, using a MBES and HISAS, further characterized the local seabed morphology. Survey results indicate a gradual increase in water depth from west to east, with recorded depths ranging from 754.08 m at the central western edge of the surveyed area to 924.08 m in the northeastern sector. The seabed is characterised by very gentle to gentle slopes, generally ranging between 0 and 10 degrees. At the Asopus-1 exploration well location, the water depth is approximately 842.5 m, with a local seabed slope of 1.3 degrees.

### 8.3.2 Seabed morphology

The macro-scale morphostructural framework of the Eastern Mediterranean includes major geological features such as the Hellenic Trench, Calabrian Arc, Apulian Escarpment, and Mediterranean Ridge (Otero

& Mytilineou, 2022). The northern Ionian Sea represents the southern continuation of the Adriatic Sea basin (Otero & Mytilineou, 2022). The Apulian Escarpment is a major structural feature, exceeding 1,000 m in height, which separates the Apulian Platform to the north from the Calabrian Arc accretionary prism to the south (Otero & Mytilineou, 2022). Along the western Greek margin, the seabed is characterized by submarine valleys and erosional features, including blind and V-shaped canyons (Otero & Mytilineou, 2022). The Asopus-1 exploration well is located on the distal sector of the Apulian Platform, away from the steep continental margins and submarine canyon systems developed further east along the Western Greek margin.

Desktop studies indicate that the local seabed morphology is influenced by a regional horst and graben tectonic setting associated with deep-seated normal faulting. This geological framework results in a step-like bathymetric profile with locally undulating and mound-like seabed features (Del Ben et al., 2015).

Results from the LOT 01 Geophysical Survey Campaign further characterized the local seabed morphology. The survey identified an articulated seafloor, with east–west oriented fault-related scarps contributing to a step-like morphology, with vertical offsets of several metres. The seabed is also affected by a mass transport deposit, characterized by elongated mound-like features oriented approximately perpendicular to the slope direction. Much of the deposit is covered by a low-reflectivity pelagic sediment layer, interpreted as fine-grained clay or silt, while locally the underlying consolidated sediments are exposed.

At the Asopus-1 well location, the mass transport deposit is exposed, forming a morphology characterized by grooves covered by fine sediments and intervening ridges composed of harder sediments, with heights ranging from approximately 0.2 to 1 m. The planned well location is situated within one of these grooves. Within a 500 m radius of the well location, harder sediment exposures locally increase seabed gradients along their flanks, with slopes reaching up to 10 degrees. No fault scarps were identified within this area.

### 8.3.3 Morphological characteristics in the terrestrial environment

With regards to the shorebase facilities, the broader study area falls within the Epirus Water District (EL05), which is one of the most mountainous regions of Greece. Mountainous areas account for approximately 70% of the total area of the Water District, while lowland areas represent approximately 15%.

Although the Port of Igoumenitsa is located within a coastal environment, the surrounding terrestrial landscape is predominantly characterized by mountainous terrain. The main exception occurs to the east, where the western margins of the Ladochori plain extend towards the port area. In this area, the lower slopes of Liotrivia Hill descend towards sea level, while the Igoumenitsa–Preveza National Road crosses the area mainly through cut sections excavated into the surrounding terrain.

### 8.3.4 Topographical Characteristics in the Terrestrial Environment

#### 8.3.4.1 Landscapes of outstanding natural beauty

Landscape is recognized as an important component of the environment and human surroundings under the European Landscape Convention, which was incorporated into Greek legislation through Law 3827/2010 (Government Gazette 30/A/25.02.2010). The Convention promotes the protection, management, and planning of landscapes, including areas of particular natural, cultural, or aesthetic value.

The Greek legislative framework provides for the designation and protection of landscapes of particular value, including Landscapes of Outstanding Natural Beauty under Law 1465/1950 and remarkable landscapes protected under Law 3937/2011 (Government Gazette 60/A/31.03.2011).

Within the study area considered for the shorebase facilities at the Port of Igoumenitsa, no designated Landscapes of Outstanding Natural Beauty or Protected Natural Monuments have been identified. According to the FILOTIS database, the nearest designated Landscape of Outstanding Natural Beauty is AT3011004 “Ekvoli Kalama”, located approximately 6.5 km southwest of the shorebase facilities.

#### 8.3.4.2 Landscapes of the Epirus region’s regional landscape area

According to the Revised Regional Spatial Framework and Landscape Strategy of the Region of Epirus (Ministerial Decision YPEN/DCHORS/78523/1208/05.11.2018, Government Gazette 286/AAP/28.11.2018), Article 14 “Landscape Strategy Directions” classifies landscapes within the Region of Epirus into four categories according to their value: International Value, National Value, Regional Value, and Particularly Degraded Landscapes.

- Landscapes of International Value: This category encompasses the Amvrakikos Gulf Area Zone, the Dodoni Valley Archaeological Site Zone, and the Nikopolis Archaeological Site Zone.
- Landscapes of National Value: This category includes the Wider Zagori Area Zone, the Wider Metsovo Area Zone, the Wider Northern Tzoumerka Area Zone, the Wider Konitsa–Mastorochochia–Grammos Area Zone, and the Wider Pogoni Area Zone.
- Landscapes of Regional Value: This category comprises the Lake Pamvotida and City of Ioannina Area Zone, the Wider Southern Tzoumerka Area Zone (Regional Unit of Arta), the Ionian Sea Coastal Zone (Regional Unit of Preveza), the Parga–Perdika–Syvota Coastal Zone, and the Kalamas Delta–Sagiada Coastal Zone.
- Particularly Degraded Landscapes: This category identifies areas requiring significant landscape rehabilitation, including the Linear Entrance Zones of the cities of Ioannina, Preveza, Arta, and Igoumenitsa. It also includes the Degraded Coastal Settlement Landscape Zone of Paralia Vrachos–Loutsa (Preveza) and the Extensive Open-Cast Extraction and Abandoned Quarry Zone of Ioannina.

The shorebase facilities are located in the wider Igoumenitsa area and are in proximity to the Linear Entrance Zone of Igoumenitsa, which is classified under the regional landscape strategy as a Particularly Degraded Landscape Zone.

#### 8.3.4.3 Areas Related to the European Landscape Convention, which was ratified by Law 3827/2010 (A’ 30)

The European Landscape Convention, also known as the Florence Convention, was ratified by Greece through Law 3827/2010 “Ratification of the European Landscape Convention” (Government Gazette 30/A/25.10.2010). The Convention aims to promote the protection, management, and planning of landscapes, as well as cooperation among European countries on landscape-related matters.

Under the European Landscape Convention, landscapes are recognized as an essential component of the human environment, reflecting the diversity of shared cultural and natural heritage and contributing to the

formation of identity. The Convention requires the establishment and implementation of landscape policies aimed at their protection, management, and planning.

According to Map P.2d of the Revised Regional Spatial Framework of the Region of Epirus, the closest Landscape Zones of Regional Value to the Project's onshore facilities are the Kalamas Delta–Sagiada Coastal Landscape Zone, located north and northwest of Igoumenitsa, and the Plataria–Syvota–Perdika–Parga Coastal Landscape Zone, extending south and southwest of the Project area.

## 8.4 Geological, tectonic, and sediment/soil characteristics

### 8.4.1 Geology in the marine environment

---

The Eastern Mediterranean Sea is characterized geologically by the convergence between the African and Eurasian plates. The Asopus-1 exploration well is located within the southern sector of the Adria Microplate, a continental lithospheric block that is distinct from the main African Plate (Tugend et al., 2019). The well is situated on the Apulian Platform, a broad carbonate domain comprising a thick Mesozoic carbonate succession, reaching up to approximately 5 km in thickness, underlain by discontinuous Permo-Triassic siliciclastic continental sediments and Burano evaporites (Tugend et al., 2019).

The local geological setting is associated with a regional extensional tectonic regime, where deep-seated normal faults have affected the Apulian Platform, resulting in a horst and graben structural framework (Del Ben et al., 2015). At the Asopus-1 drilling location, the seabed is characterized by a very thin cover of post-Miocene sediments, with potential local structural influences associated with Messinian evaporite formations.

### 8.4.2 Sediment

---

The sedimentary history of the northern Ionian Basin reflects a long stratigraphic evolution, with sediment deposition influenced by regional tectonic processes and characterized by turbiditic and gravity-driven deposits (Tugend et al., 2019). At the basin scale, superficial seafloor mapping indicates that the wider Project area is predominantly characterized by mud and muddy sand sediments (Spatola et al., 2025).

#### 8.4.2.1 Physicochemical measurements and macroscopic description

---

Field measurements performed immediately after sample recovery indicated sediment temperatures of 13.5 – 15.6 °C, limited pH variability (7.79 – 7.93) and consistently negative ORP values (–169.4 to –120.9 mV), indicative of reducing conditions typical of fine-grained marine sediments. Macroscopic observations suggested highly homogeneous sedimentological conditions throughout the study area, with sediments generally described as “Clayey silt”, medium hydrated, odourless and devoid of shell fragments, plant remains or other noteworthy features.

#### 8.4.2.2 Grain-size and other physic-chemical variables

Grain-size laboratory analyses confirmed the absence of Gravel from all samples, while sand generally represented a minor fraction (< 15 %), except at Italy Ref (23.5 %). Pelitic fractions clearly predominated throughout the study area, with Silt and Clay together accounting for approximately 86 – 100% of the sediment matrix. According to both Folk and Shepard classifications, sediments were predominantly assigned to the “Mud” and “Silty clay” classes, respectively, confirming the granulometric homogeneity of the study area, with Italy Ref exhibiting a slightly coarser texture. Among the other physic-chemical variables investigated in the sediment samples, moisture content showed moderate variability across the study area, with generally higher values at Northern station group, Blank and Reference Stations than around Asopus-1, whereas sediment density remained remarkably uniform, reflecting the overall homogeneity of the investigated fine-grained deposits.

#### 8.4.2.3 Total Organic Carbon (TOC) and nutrients

TOC concentrations were generally low and frequently below the analytical LoQ (0.1 % d.s.), while carbonate contents exhibited limited spatial variability and consistently moderate concentrations. N-Tot and P-Tot also showed relatively homogeneous distributions across the study area, with no clear differences between well-site, Blank and Reference Stations. Overall, the investigated sediments were characterized by low organic-matter content and relatively uniform nutrient concentrations.

#### 8.4.2.4 Metals and metalloids

Among metals and metalloids, Cr VI remained consistently below the LoQ, whereas Sn and Hg were only sporadically detected at very low concentrations. Al and Fe were by far the most abundant elements, reflecting their predominantly lithogenic origin, while the remaining investigated metals generally occurred at concentrations within the order of magnitude of  $10^1$  mg kg<sup>-1</sup> d.s. Spatial variability was generally limited, although Northern station group tended to exhibit slightly higher concentrations than Asopus-1 station group and the Blank stations, while Italy Ref frequently showed comparatively lower values. Exceedances of the applicable reference values were identified for As, Ni and Cr-Tot. As exceeded both the HCMR ERL values and, at selected stations, the Italian SQA-MA (D.Lgs. 172/2015, Table 3/B), whereas Ni exceeded the HCMR ERL threshold throughout the study area. Cr-Tot exceeded the Italian SQA-MA (D.Lgs. 172/2015, Table 3/B) at a limited number of stations. All remaining investigated metals and metalloids showed concentrations always below the applicable regulatory reference values.

#### 8.4.2.5 Total Petroleum Hydrocarbons (TPH) and Polycyclic Aromatic Hydrocarbons (PAHs)

Hydrocarbon concentrations in surface sediments were generally low throughout the study area. The light hydrocarbon fraction ( $C \leq 12$ ) remained below the analytical LoQ at all stations, whereas the heavier fraction ( $C > 12$ ) and the corresponding TPH were consistently detected at low concentrations, showing limited spatial variability and no evident differences among well-site, Blank and Reference Stations; the only exception was Italy Ref, where both  $C > 12$  hydrocarbons and TPH remained below the LoQ.

Most investigated PAHs were below the analytical LoQ at all stations. Only a limited number of compounds were sporadically detected, mainly Fluoranthene and Pyrene, which represented the most frequently quantified PAHs, occurring at four and five stations, respectively. The highest individual concentrations were recorded for Benzo(b)fluoranthene and Benzo(g,h,i)perylene at Italy Ref, and for Fluoranthene at D6a. Detectable PAHs were confined to a small number of stations, with the highest diversity of quantified compounds and the highest  $\Sigma$  PAHs concentration observed at Italy Ref, followed by the Blank station D6a, where a lower but still comparatively elevated  $\Sigma$  PAHs concentration was recorded. All remaining stations showed either no quantifiable PAHs or only isolated detections, resulting in substantially lower  $\Sigma$  PAHs values and no consistent spatial pattern among well-site, Blank and Reference Stations.

All measured concentrations of petroleum hydrocarbons (including both hydrocarbon fractions and TPH) and PAHs (including  $\Sigma$  PAHs) remained below the applicable reference values adopted in Greece (ERL, HCMR; Long et al., 1995) and the Italian Environmental Quality Standards (SQA-MA; D.Lgs. 172/2015). The results do not indicate hydrocarbon contamination within the investigated sediments.

#### 8.4.2.6 Microplastics in the sediment

Microplastics were not detected in any sediment sample collected at the Asopus-1 station group and Northern station group, the Blank stations, or the Reference Stations. This consistent result across all investigated station groups indicates that no microplastics were detected within the analysed sediment samples and provides no evidence of significant microplastic contamination at the time of sampling. Although no regulatory threshold values are currently available for microplastics in marine sediments under the Greek or Italian frameworks considered in the present study, the absence of detectable particles at all stations provided no indication of significant microplastic accumulation within the investigated seabed.

#### 8.4.3 Geological characteristics in the terrestrial environment

The broader area surrounding the Port of Igoumenitsa is located within the sedimentary domain of the Ionian geotectonic zone, which extends in a predominantly north-south direction along the western margin of mainland Greece. The zone covers much of Epirus, Acarnania, parts of the Ionian Islands, and areas of the northwestern Peloponnese.

According to current geological interpretations, the Adriatic-Ionian (Ionian) Zone is considered an autochthonous unit, overthrust by more internal geotectonic zones forming tectonic nappes. The autochthonous unit is locally exposed through tectonic windows and, in some areas, double tectonic windows. The Ionian Zone represents a continental basin characterized by hemipelagic to pelagic sedimentation.

Within the Region of Epirus, formations of the Ionian Zone constitute the dominant geological units. These formations are unconformably overlain by Neogene deposits, including marls, marly limestones, and conglomerates, as well as Quaternary deposits comprising alluvial sediments, terrace deposits, talus and slope debris, and coastal formations.

#### 8.4.4 Hydrogeology

The onshore facilities of the Port of Igoumenitsa are located along the coastal margin of the Filiates–Igoumenitsa Groundwater Body (EL050A070), which forms part of the Kalamas River Basin (EL0512) according to the Second Revision of the River Basin Management Plan for the Epirus River Basin District (EL05).

The principal aquifer systems within the Kalamas River Basin are developed in the carbonate formations of the Ionian Zone and discharge through discrete springs. Sinkholes play an important role in the recharge of these karst aquifer systems by draining the closed hydrological basins.

Aquifers of lower significance also occur within the granular formations of the Quaternary deposits. Their groundwater potential depends primarily on the grain-size distribution of the sediments and the prevailing recharge conditions.

Significant areas of recent unconsolidated deposits and Triassic breccias with gypsum are also present, while flysch formations generally constitute formations of lower permeability. Groundwater recharge occurs primarily through the direct infiltration of precipitation into the carbonate formations and, secondarily, through infiltration from streams and rivers. The mean annual recharge is estimated at approximately 171.41 million m<sup>3</sup>/year.

#### 8.4.5 Soil characteristics

According to the Soil Map of Greece available through the Geospatial Information Portal of the Ministry of Environment and Energy, the wider study area surrounding the Port of Igoumenitsa includes several soil-mapping associations. Coastal and low-lying areas are primarily characterised by young alluvial and coastal soils, while the surrounding hilly areas are dominated by shallow, calcareous soils developed over the carbonate formations of the Ionian Zone. Locally, soils associated with colluvial deposits, flysch formations, and other fine-grained geological units are also present.

#### 8.4.6 Tectonic characteristics

The tectonic framework of the Eastern Mediterranean is associated with the convergence between the African (Nubian) and Eurasian tectonic plates. The region is characterized by high tectonic complexity due to the presence of major subduction systems, including the Hellenic subduction zone south of Greece and the Calabrian subduction zone south of Italy. The Apulian Platform and Ionian Sea form part of the broader Ionian–Apulian domain, which undergoes ongoing deformation associated with the relative motion and rotation of the Adria Microplate with respect to the African Plate.

The geological evolution of the wider area reflects a complex geodynamic history from the Permian to the Quaternary. During the Permian to Middle Triassic, extensional processes resulted in the formation of the Ionian sedimentary basin, followed by Tethyan rifting during the Late Triassic to Early Jurassic, which generated regional fault systems and fragmentation of the carbonate platform. Subsequent tectonic reorganization during the Tortonian to Early Messinian resulted in a compressional regime and reactivation

of inherited structures. During the Plio-Quaternary, continued tectonic deformation associated with regional convergence contributed to the present-day structural configuration of the Ionian–Apulian domain.

The Asopus-1 exploration well is located in the southern sector of the Adria Microplate, on the structurally elevated Apulian Platform. The local geological setting is characterized by deep-seated normal faults affecting the carbonate platform, resulting in a horst and graben structural framework and the development of associated sedimentary basins and syn-tectonic mass transport deposits.

Although the wider region is tectonically active, the Asopus-1 well location is situated away from the main active compressional zones associated with the Hellenic and Calabrian subduction systems. Sub-bottom profiler data acquired during the LOT 01 Geophysical Survey Campaign indicate the presence of buried fault structures with offsets of several metres, however, no corresponding fault scarps or measurable fault-related displacements were identified at the seabed within a 500 m radius of the well location. The local seabed morphology therefore does not show evidence of recent tectonic deformation mapped at the survey scale.

Regarding the onshore component of the Project, the wider Igoumenitsa area is classified within Seismic Zone II according to the Amendment of the Provisions of the Greek Anti-Seismic Regulation EAK 2000 due to the Revision of the Seismic Hazard Map (Government Gazette 1154/B/12.08.2003). For this seismic zone, the design ground acceleration coefficient is defined as  $\alpha = 0.24$ , where the maximum horizontal ground acceleration is expressed as  $A = \alpha \times g$ , with  $g$  representing gravitational acceleration.

#### 8.4.7 Geo-hazards

Predictive landslide susceptibility mapping available through the European Marine Observation and Data Network (EMODnet) indicates that the Project area is characterized by low susceptibility to gravity-driven mass movements, associated with the generally gentle bathymetric gradients of the distal Apulian Platform (Innocenti et al., 2020). Based on regional seismotectonic information, the potential for tsunami generation directly at the well location is considered low, given the distance from the main active subduction zones of the Hellenic Arc and the absence of steep local bathymetric gradients typically associated with major submarine slope failures. Volcanic activity in the Mediterranean is primarily associated with the Tyrrhenian and Aegean regions, while deep-sea mud volcanoes are mainly distributed along the Mediterranean Ridge and Calabrian Arc. No volcanic features have been identified within the vicinity of the Asopus-1 well location.

Regarding fluid-escape features, regional predictive models (Spatola et al., 2025) indicate that the wider Project area falls within a zone of variable pockmark susceptibility, related to the presence of fault systems that may provide pathways for fluid migration. However, available desktop information and geophysical data do not indicate mapped pockmarks or active gas seepage at the well location. Review of existing offshore infrastructure indicates that no oil and gas or renewable energy installations are present within a 100 km radius of the well location. International submarine telecommunication cables are present within the wider region, including the planned Eagle system and the operational Jonah and AAE-1 systems. Bathymetric and acoustic data acquired during the LOT 01 Geophysical Survey Campaign identified the closest cable, AAE-1, at a minimum distance of approximately 2,692 m from the well location.

Sub-bottom profiler data acquired during LOT 01 indicate that the shallow subsurface within a 500 m radius of the Asopus-1 well trajectory is primarily characterized by chaotic seismic facies associated with a mass transport deposit, classified as seismic facies F2. At the well location, this unit has an estimated thickness

of 18.62 m and is underlain by a medium-reflectivity horizon (R3) identified at approximately 19.72 m below seabed. Although a pelagic sediment cover is present regionally, within the immediate well area the fine-grained sediment cover within seabed grooves is too thin to be distinguished as separate seismic facies.

Localized acoustic blanking features (wipe-out zones) were identified within the 500 m assessment area, beginning at approximately 8 m below seabed. The closest identified anomaly is located approximately 243 m from the well location at a bearing of 214°. These features may be associated with fluid-related processes, including dewatering within the deformed mass transport deposit material, although their precise origin cannot be confirmed from the available data.

Overall, the available surface and sub-surface investigations did not identify evidence of active gas seepage, gas chimneys, active pockmarks, acoustic plumes, mud volcanoes, or gas hydrates within the surveyed Project area. Furthermore, no fault-related seabed displacement or fault scarp morphology was identified within the 500 m area surrounding the well trajectory.

## 8.5 Natural environment

### 8.5.1 General characteristics

#### 8.5.1.1 Benthic habitats

Available literature indicates that the deep-sea benthic environment of the Eastern Ionian Sea is predominantly characterised by soft-sediment habitats composed of fine-grained muddy and silty-clay sediments. These deep-water environments support benthic communities adapted to oligotrophic conditions, relatively stable deep-water temperatures, and elevated salinity. Certain bathyal habitats within the Eastern Ionian Sea support Vulnerable Marine Ecosystems, associated with fragile, slow-growing, habitat-forming sessile species. Documented deep-water coral assemblages include bamboo corals, such as *Isidella elongata*, and black corals, including *Leiopathes glaberrima* and *Antipathes dichotoma*, which are typically associated with deep-sea soft sediments at depths of approximately 300–1,000 m. While cold-water coral habitats are known from other areas of the Mediterranean, no evidence of living cold-water coral reef structures has been reported from the Eastern Ionian Sea.

Consistent with the conditions described for the Eastern Ionian Sea, AUV observations and macrozoobenthic analyses indicate that the seabed within the study area is largely homogeneous and dominated by the Mediterranean Upper Bathyal Mud biocoenosis (EUNIS code: ME65). This habitat is characterised by fine-grained sediments supporting benthic communities adapted to deep-water conditions. Observations included evidence of burrowing and tubicolous organisms, occasional deep-sea fish species belonging to the family Macrouridae, and local areas associated with the burrowing sea anemone *Andresia partenopea*.

A limited rocky substrate area corresponding to the Mediterranean Upper Bathyal Rock biocoenosis (EUNIS code: ME15) was identified at station D4a. This hard-substrate habitat supported deep-water coral assemblages associated with *Antipathella subpinnata* and/or *Callogorgia verticillata*, representing a localised increase in habitat diversity within the predominantly soft-sediment bathyal environment.

### 8.5.1.2 Macrozoobenthos community

Based on regional literature, the deep-sea benthic environment of the Eastern Ionian Sea supports biological assemblages specifically adapted to oligotrophic conditions, deep-water homothermy, and high salinity. The structure of these communities in Mediterranean bathyal environments is strongly controlled by the reduced downward flux of particulate organic carbon (POC) to the seafloor. Under such conditions, macrobenthic biomass and diversity are naturally low, and communities are typically dominated by opportunistic and tolerant taxa, particularly annelids and nematodes, which are better adapted to limited trophic availability. Furthermore, the fine granulometry of these bathyal sediments reduces interstitial circulation and promotes low redox potential conditions, which naturally limits the occurrence of more sensitive taxa, such as many molluscs and peracarid crustaceans.

Consistent with this regional desktop baseline, analyses of macrobenthic communities revealed an overall homogeneous ecological structure across the Asopus-1 station group and Northern station group, Blank stations, and Reference Stations, with no statistically significant differences among station groups. The observed variability was primarily attributable to natural small-scale heterogeneity of the sedimentary environment

Benthic communities were characterized by low abundance, reduced species richness, and limited diversity, confirming the conditions typically observed in oligotrophic Mediterranean bathyal environments. The ecosystem was dominated by the Mediterranean Upper Bathyal Mud biocenosis (EUNIS code: ME65). A total of 116 individuals belonging to 19 taxa were recorded, with Annelida overwhelmingly dominating both abundance (94.8 %) and species richness (73.7 %). Community structure was largely dominated by the sipuncula *Golfingia* sp., a taxon commonly associated with fine-grained bathyal sediments.

Ecological-quality indices reflected the naturally low-diversity character of these deep-sea communities. M-AMBI values ranged from “Bad” to “Moderate”, whereas AMBI classified most stations as “Undisturbed”, with only isolated cases of “Slightly” or “Moderately disturbed” conditions. Overall, the results were consistent with a naturally oligotrophic bathyal ecosystem rather than with evidence of ecological disturbance.

### 8.5.1.3 Plankton

Regional literature characterizes the Ionian Sea as a highly oligotrophic basin, where nutrient depletion in surface waters limits primary production and supports plankton communities typical of offshore marine environments. Phytoplankton assemblages are generally dominated by small-sized microalgae (<10 µm), although occasional occurrences of Indo-Pacific diatoms (e.g., *Chaetoceros bacteriaströides*) and rare dinoflagellates (e.g., *Gynogonadinium aequatoriale*) have been reported. Historical studies also indicate that episodic blooms of siliceous phytoplankton contribute to intermittent vertical fluxes of particulate organic matter. Similarly, mesozooplankton communities are characterized by relatively low biomass but high taxonomic diversity, with holoplanktonic taxa, particularly copepods, dominating offshore waters under the influence of the basin's oligotrophic conditions and hydrological stratification. Ichthyoplankton assemblages are likewise representative of deep offshore environments and are typically dominated by mesopelagic and bathypelagic species associated with deep scattering layer communities rather than coastal fish assemblages.

The survey results of LOT 02 were consistent with this regional baseline. The phytoplankton community exhibited significant differences among the three sampling depths (surface, middle and bottom), indicating that light availability is an important factor controlling its vertical distribution. Significant spatial variability was also observed among the Asopus-1, northern, Blank and Reference station groups, reflecting natural environmental variability. The community was dominated by the "Other taxa" category, comprising primarily Cryptophyceae and unidentified microflagellates (<10 µm), while Bacillariophyceae (diatoms) represented the second most abundant group, mainly due to the widespread occurrence of the *Pseudo-nitzschia delicatissima* complex together with species such as *Thalassionema nitzschioides*. Numerous dead cells of *P. delicatissima* were recorded, suggesting the recent decline of a bloom event. Dinophyceae and Coccolithophyceae, including *Gephyrocapsa huxleyi*, were less abundant and less diverse, consistent with offshore oligotrophic conditions.

The mesozooplankton community displayed high taxonomic diversity and a homogeneous spatial distribution across all sampling stations, with no significant differences between the Asopus-1, northern and Reference station groups. Community composition was dominated by copepods, including abundant calanoid species such as *Clausocalanus paululus* and *Haloptilus longicornis*, together with less common deep-water taxa including *Arietellus pavoninus* and *Augaptilus glacialis*. Other characteristic holoplanktonic organisms included pteropods (*Cavolina* sp.), pelagic polychaetes (*Tomopteris* sp.), euphausiids and bathypelagic amphipods (*Anchylomera blossevillei*). In contrast, meroplankton was only sparsely represented by larval forms such as Brachiolaria and Auricularia, indicating a negligible influence from coastal environments.

The ichthyoplankton assemblage was similarly representative of deep pelagic offshore ecosystems. The community was dominated by mesopelagic and bathypelagic species typical of oligotrophic waters, including *Cyclothone braueri*, *Maurolicus muelleri*, myctophids such as *Hygophum benoiti* and *Lampanyctus pusillus*, and paralepidids including *Arctozenus risso* and *Paralepis coregonoides*. Coastal taxa were scarce, with the epipelagic component represented primarily by larvae of the European sardine (*Sardina pilchardus*) and unidentified Scombridae. Overall, the plankton communities recorded during the survey were consistent with the natural ecological characteristics of the deep offshore Ionian Sea and showed no evidence of unusual community structure or anthropogenic influence.

#### 8.5.1.4 Fish fauna

Based on global geographic range data from the IUCN database, 371 marine fish species are identified within the wider project area, comprising 310 ray-finned fishes, 60 cartilaginous fishes, and 1 lamprey species. Field analyses of ichthyoplankton from the immediate area recorded low species diversity and abundance, consistent with the characteristics of an open-ocean, deep pelagic environment with limited influence from neritic inputs. The larval assemblage was dominated by the epipelagic species *Sardina pilchardus* and larvae of the family Scombridae. The remaining diversity was primarily represented by mesopelagic taxa, including *Cyclothone braueri*, *Maurolicus muelleri*, and representatives of the family Myctophidae, such as *Hygophum benoiti* and *Lampanyctus pusillus*. Species associated with meso- to bathypelagic environments, including the paralepidids *Arctozenus risso* and *Paralepis coregonoides*, were also recorded, reflecting their broad vertical distribution across intermediate and deeper water layers.

Near the seabed, AUV visual surveys confirmed the presence of deep-sea fishes belonging to the family Macrouridae associated with the muddy bathyal seafloor. The deep waters of the study area support

characteristic bathyal fish assemblages, including cartilaginous species such as the blackmouth catshark (*Galeus melastomus*), longnose skate (*Dipturus oxyrinchus*), and longnose spurdog (*Squalus blainville*). Additional obligate deep-water species, including the rabbitfish chimaera (*Chimaera monstrosa*), velvet belly lanternshark (*Etmopterus spinax*), and kitefin shark (*Dalatias licha*), are documented from depths exceeding 200 m.

Environmental DNA (eDNA) metabarcoding analyses conducted across the study area further were confirmed with the presence of both demersal and pelagic fish assemblages characteristic of the northern Ionian Sea. Despite the rapid dilution of genetic material expected in open pelagic environments, the survey detected several commercially and ecologically important species, including European hake (*Merluccius merluccius*), European anchovy (*Engraulis encrasicolus*), and black-bellied angler (*Lophius budegassa*). The common sole (*Solea solea*) was detected across all study-area categories and exhibited the highest number of sequence reads among the identified vertebrate taxa. The detection of lanternfishes (*Hygophum* sp.) further supports the presence of deep-sea mesopelagic and bathypelagic communities expected within the bathyal waters of the wider area.

#### 8.5.1.5 Marine mammals

Available literature and existing datasets indicate that the wider Ionian Sea and the Hellenic Trench margin support a diverse assemblage of marine mammals (Notarbartolo di Sciara, 2016), although species occurrence and density vary spatially and temporally across the region. Documented species include deep-diving cetaceans such as the sperm whale (*Physeter macrocephalus*), classified as Endangered (EN) at the Mediterranean regional level, and Cuvier's beaked whale (*Ziphius cavirostris*), classified as Vulnerable (VU) (Notarbartolo di Sciara et al., 2012; Holcer et al., 2007; Thompson et al., 2023; IUCN, 2023). The area also supports the fin whale (*Balaenoptera physalus*), the only resident baleen whale in the Mediterranean Sea, which is classified as Endangered (EN). Furthermore, several delphinid species occur in the area, including the striped dolphin (*Stenella coeruleoalba*), classified as Least Concern (LC); Risso's dolphin (*Grampus griseus*), classified as Endangered (EN); the short-beaked common dolphin (*Delphinus delphis*), classified as Endangered (EN); the common bottlenose dolphin (*Tursiops truncatus*), classified as Vulnerable (VU); and the rough-toothed dolphin (*Steno bredanensis*), classified as Near Threatened (NT) (Bearzi et al., 2011; Carlucci et al., 2017; IUCN, 2023). Records of the Mediterranean monk seal (*Monachus monachus*), classified as Endangered (EN), are also available from the wider area (Notarbartolo di Sciara et al., 2009; IUCN, 2023). These species are subject to strict protection under Annex IV of the EU Habitats Directive (Council Directive 92/43/EEC). In addition, the Mediterranean monk seal (*Monachus monachus*) is listed under Annex II of the Directive, requiring the designation of Special Areas of Conservation. Cetacean species are also covered by relevant international conservation agreements, including ACCOBAMS, the Bern Convention, CITES, and the Convention on Migratory Species (CMS), while the Mediterranean monk seal is protected under relevant international conservation frameworks, including the Bern Convention, CITES, and CMS.

Dedicated marine fauna observations were undertaken during both the LOT 01 and LOT 02 campaigns to characterise marine mammal presence. The observations also supported the implementation of survey mitigation measures in accordance with ACCOBAMS guidance.

During LOT 01, a total of 373 hours and 14 minutes of monitoring effort was completed, comprising 223 hours and 58 minutes of daylight visual observations and 149 hours and 16 minutes of nighttime Passive Acoustic Monitoring using a towed hydrophone array and PAMGuard software. Visual observations identified striped dolphins and unidentified delphinids in the vicinity of the survey vessel. In parallel, analysis of autonomous hydrophone recordings from the offshore mooring system identified sperm whale vocalisations on most monitoring days and at least 13 acoustic encounters attributed to Cuvier's beaked whales during the analysed dataset.

During LOT 02, visual observations were conducted during daylight hours, with Passive Acoustic Monitoring undertaken during nighttime periods and reduced visibility conditions. Marine mammal observations included a single adult Risso's dolphin recorded on 27 March in approximately 800 m water depth and a solitary adult sperm whale observed on 28 March in approximately 850 m water depth. The sperm whale was subsequently acoustically tracked during a dive reaching approximately 750 m depth. Additional acoustic detections included two nocturnal dolphin encounters on 15 March, characterised by clicks and burst pulses in the 30–48 kHz frequency range, and a potential sperm whale detection on 31 March.

#### 8.5.1.6 Sea turtles

Desktop studies indicate that the broader Ionian Sea serves as an important migratory, developmental, and year-round foraging area for sea turtles across various life stages (Casale et al., 2018; Papazekou et al., 2024). The region supports nesting and foraging populations of the loggerhead turtle (*Caretta caretta*), which is classified as Vulnerable (VU) globally and Least Concern (LC) at the Mediterranean regional level, and the green turtle (*Chelonia mydas*), classified as Least Concern (LC) globally and Near Threatened (NT) at the Mediterranean regional level (IUCN, 2023; Hochscheid et al., 2019). Additionally, the leatherback turtle (*Dermochelys coriacea*), classified as Vulnerable (VU) globally, is regularly recorded as a non-breeding visitor to the Mediterranean basin. While adult turtles of these species exhibit a strong preference for neritic habitats (generally defined as waters over the continental shelf, typically extending to the 200 m isobath) for foraging and wintering, satellite telemetry indicates that the deep pelagic waters of the Ionian Sea function as important migratory corridors (Casale et al., 2018). Tracking data indicates that that post-nesting loggerhead turtles transit through the Ionian Sea, including the Strait of Otranto when moving between Mediterranean habitats and northern Adriatic foraging grounds. Due to the spatial overlap between these migratory corridors and regional fishing effort, sea turtles are highly vulnerable to anthropogenic mortality, primarily through incidental fisheries bycatch, entanglement, and marine litter ingestion, as reflected by high stranding rates along the Ionian coasts of Greece and Italy (Despoti et al., 2025; Papazekou et al., 2024). These species are subject to strict protection under Annex IV of the EU Habitats Directive and are also protected under CITES, the Convention on Migratory Species (CMS), and Annex II of the SPA/BD Protocol.

Field observation efforts conducted across the LOT 01 and LOT 02 campaigns confirmed the presence of sea turtles utilizing the deep-water offshore project area. During the LOT 01 visual daylight observations, two specific encounters were documented: on April 8, an unidentified sea turtle (likely a loggerhead) was observed swimming slowly near the vessel before diving, and on April 12, an adult male loggerhead sea turtle (identified by its extended tail) was recorded swimming parallel to the vessel at a range of 25 m (Lighthouse SpA, 2026). During the subsequent LOT 02, an additional visual sighting of a single large adult loggerhead sea turtle occurred in 700 meters of water on March 30.

### 8.5.1.7 Avifauna

Desktop data and results of field surveys indicate that the wider Ionian Sea forms part of the Black Sea-Mediterranean Migratory Bird Flyway. The offshore pelagic waters are utilised by pelagic seabird species such as Scopoli's Shearwater (*Calonectris diomedea*), Yelkouan Shearwater (*Puffinus yelkouan*), and European Storm-petrel (*Hydrobates pelagicus*), as well as by more coastal species including Audouin's Gull (*Larus audouinii*) and Mediterranean Gull (*Larus melanocephalus*), for foraging, post-breeding dispersal, return movements to breeding sites, and migratory transit. Telemetry data show that Scopoli's Shearwaters breeding on nearby islands traverse the Project area during foraging trips. However, the primary migratory corridors for soaring birds, waterbirds, and passerines are concentrated along the coastal areas and island chains rather than the open sea. It should be noted that the available bibliographic and field survey data for the survey area are very limited and do not allow firm conclusions to be drawn regarding the autumn migration and wintering periods.

The project area does not overlap with any Special Protection Area (SPA), Important Bird Areas (IBAs) or breeding colonies; the nearest designated SPAs and IBAs, such as the Diapontia Islands, are located approximately 50 km to the east. This however should be considered with caution, as both Greece and Italy are currently in a process filling the knowledge gaps regarding the birds, marine mammals and sea turtles in the offshore marine environment and identifying marine hotspots to be proposed for inclusion in the Natura 2000 network of protected areas (LIFE MareNatura).

Avifauna visual observations were carried out during daylight hours over a 10-day period, spanning from March 14 to March 16, 2026, and from March 26 to April 1, 2026. The total duration of the visual observations was 115 hours. The survey vessel travelled a total distance of 1,198.9 kilometers, out of which the visual observations were conducted along transects with a total length of 330.5 kilometers. A total of 43 bird species or species groups were visually recorded across the surveyed areas. Scopoli's Shearwater was the most abundant seabird species, with 53 individuals recorded in the immediate survey area and 27 in the wider Block 2 area. Recorded Scopoli's Shearwaters were primarily travelling towards the Ionian coast of Italy, where species important foraging areas are located, therefore it is considered that the main species behaviour in the immediate survey area and in the Block 2 area is traversing the areas towards/from their foraging areas. The second most abundant species in the immediate survey area (48 individuals recorded) and the Block 2 area was the Mediterranean Gull, which is considered to be using the area for migration/passage towards its breeding areas. Yelkouan shearwaters were not recorded in the immediate survey area or Block 2, with sightings restricted mainly to the coastal areas outside Block 2. Audouin's Gulls were recorded in the pelagic areas, including six individuals in the immediate survey area and two in Block 2, primarily consisting of immature individuals in pre-breeding passage. Additional species observed in the immediate survey area and Block 2 on spring migration included waterbirds such as the Garganey, herons such as the Great Egret and Grey Heron, waders such as the Eurasian Curlew, and raptors including the Western Marsh Harrier, Lesser Kestrel, and Common Kestrel. The presence of these species in the pelagic areas indicates use of the area during spring migration. Furthermore, 14 migratory passerine species were recorded in the immediate survey area and Block 2 during the survey period. Under the weather conditions during the field surveys the majority of observed passerines utilized the survey vessel as a temporary stopover for resting.

## 8.5.2 Areas of the National System of Protected Areas

### 8.5.2.1 Natura 2000 Network

The closest Natura 2000 sites to the Asopus 1 exploration well site are the Marine area of the Diapontia islands Special Area of Conservation (SAC) (GR2230010) and the Diapontia Islands: Othoni, Ereikousa, Mathraki and rocky islets Special Protection Area (SPA) (GR2230008), both located approximately 41 km northeast from the Project. The SAC encompasses shallow waters characterised by *Posidonia oceanica* beds, reefs, and sea caves. The SPA supports breeding seabirds and migratory bird populations, specifically recording species such as the peregrine falcon (*Falco peregrinus*), corncrake (*Crex crex*), European turtle dove (*Streptopelia turtur*), purple heron (*Ardea purpurea*), common buzzard (*Buteo buteo*), Scopoli's shearwater (*Calonectris diomedea*), Yelkouan shearwater (*Puffinus yelkouan*), European storm-petrel (*Hydrobates pelagicus*), and Audouin's gull (*Larus audouinii*).

The Costa Otranto - Santa Maria di Leuca SAC (IT9150002) is located approximately 53 km northwest of the exploration well in Italy. The site contains *Posidonia oceanica* beds, reefs, vegetated sea cliffs, and Mediterranean temporary ponds. Protected fauna within this site includes the Mediterranean monk seal (*Monachus monachus*), Apennine yellow-bellied toad (*Bombina pachypus*), blue rock thrush (*Monticola solitarius*), long-fingered bat (*Myotis capaccinii*), and little bustard (*Tetrax tetrax*).

The Ugento Coast SAC (IT9150009) is located in Italy at a distance of approximately 66 km northwest from the exploration well. The species designated for this site include the Apennine yellow-bellied toad (*Bombina pachypus*), four-lined snake (*Elaphe quatuorlineata*), and European ratsnake (*Zamenis situla*).

The Gallipoli Coast and St. Andrea Island SPA/SAC (IT9150015) is located approximately 80 km northwest from the well. The area includes *Posidonia oceanica* beds, coastal lagoons, reefs, and vegetated sea cliffs. Documented species within this location include the common bottlenose dolphin (*Tursiops truncatus*), loggerhead turtle (*Caretta caretta*), greater horseshoe bat (*Rhinolophus ferrumequinum*), Apennine yellow-bellied toad (*Bombina pachypus*), four-lined snake (*Elaphe quatuorlineata*), Audouin's gull (*Larus audouinii*), common kingfisher (*Alcedo atthis*), and numerous wetland birds.

### 8.5.2.2 Ionian Marine National Park

The Ionian Marine National Park provides a unified spatial management framework for the marine environment of western Greece. Its scientific and regulatory basis was established through a Special Environmental Study, approved by the Hellenic Ministry of Environment and Energy on 29 December 2025. The park covers a marine area of approximately 17,691 km<sup>2</sup> and associated terrestrial areas of approximately 21 km<sup>2</sup>. It extends from the waters north of Lefkada to the island of Antikythera, including the 12-nautical-mile territorial waters from the northern Ionian Sea to Cape Tainaro and the 6-nautical-mile zone east of Cape Tainaro. The park incorporates 24 existing Natura 2000 sites, including 16 sites with marine components, aiming to enhance ecological connectivity among existing protected areas.

The zoning framework of the park was developed based on available scientific information on marine habitats and species, while considering existing maritime activities and uses. The protected area includes

important marine habitats, including *Posidonia oceanica* meadows, marine caves, and deep-sea habitats associated with biogenic structures and coralligenous communities.

The park includes extensive areas of the Hellenic Trench and supports habitats used by marine fauna for feeding, reproduction, and migration. Protected marine mammal species occurring within the wider area include the Mediterranean monk seal (*Monachus monachus*), sperm whale (*Physeter macrocephalus*), and Cuvier's beaked whale (*Ziphius cavirostris*). The area also supports delphinid species, including common dolphin and bottlenose dolphin, and includes important habitats for the loggerhead sea turtle (*Caretta caretta*).

The Ionian Marine National Park is located approximately 150 km northeast of the Asopus-1 exploration well.

### 8.5.2.3 National parks

The proposed shorebase facilities at the Port of Igoumenitsa are located outside the boundaries of designated National Parks. The nearest National Parks are the Amvrakikos National Park, located approximately 45 km southeast of the port, and the Pindus National Park, located approximately 55 km northeast.

### 8.5.2.4 Wildlife refuges

The area surrounding the proposed shorebase facilities at the Port of Igoumenitsa does not include any designated Wildlife Refuges (Καταφύγια Άγριας Ζωής). The nearest designated site is the K237 "Varathi (Mavroudi–Nea Selekeia–Igoumenitsa)" Wildlife Refuge, located approximately 2 km north of the port, followed by the K906 Wildlife Refuge, located approximately 4 km northwest.

### 8.5.2.5 Aesthetic forests

No aesthetic forests are identified within the wider study area surrounding the Project's shorebase facilities at the Port of Igoumenitsa.

## 8.5.3 Forests and woodlands

The shorebase facilities of the Project do not fall within the boundaries of the ratified and published forest map of Igoumenitsa (Initial Ratified Forest Map under Article 17 of Law 3889/2010, as amended and in force, approved by Government Gazette 531/D/24 December 2018). The ratified forest maps for the wider study area surrounding the shorebase facilities have not yet been published, however, available information is provided through the official website of the Hellenic Cadastre. According to these maps, areas located to the northwest, south, and east of the shorebase facilities are classified as forests and forest lands.

## 8.5.4 Other significant natural areas

### 8.5.4.1 Ecologically or Biologically Significant Marine Areas (EBSAs)

The closest EBSA to the Project area is the South Adriatic Ionian Strait EBSA, within which the Asopus-1 exploration well is located. The EBSA encompasses the transition zone between the southern Adriatic Sea and the northern Ionian Sea, including the Otranto Channel, with water depths ranging approximately from 200 m to 1,500 m. The designation recognizes the ecological importance of the area as habitat for Cuvier's beaked whale (*Ziphius cavirostris*), giant devil ray (*Mobula mobular*), striped dolphin (*Stenella coeruleoalba*), Mediterranean monk seal (*Monachus monachus*), and loggerhead sea turtle (*Caretta caretta*). The area also supports highly migratory species, including tuna (*Thunnus thynnus*) and swordfish (*Xiphias gladius*), as well as pelagic sharks and deep-sea benthic communities, including cold-water corals and sponge aggregations.

The Hellenic Trench EBSA is located further south of the Project area, approximately 187 km from the Asopus-1 exploration well. It extends along the Hellenic Arc and Trench system and is recognized as an important habitat for deep-diving cetaceans, particularly the sperm whale (*Physeter macrocephalus*) and Cuvier's beaked whale (*Ziphius cavirostris*), as well as other marine mammals including the Mediterranean monk seal (*Monachus monachus*), short-beaked common dolphin (*Delphinus delphis*), and common bottlenose dolphin (*Tursiops truncatus*).

### 8.5.4.2 Important Marine Mammal Areas (IMMAs)

The closest designated Important Marine Mammal Area (IMMA) to the project area is the Ionian Archipelago IMMA, located approximately 37 km east of the Asopus-1 exploration well. It is formally designated based on the presence and ecological requirements of the common dolphin (*Delphinus delphis*) and the Mediterranean monk seal (*Monachus monachus*). Furthermore, the area supports an assembly of other documented marine mammal species, including the fin whale (*Balaenoptera physalus*), the common bottlenose dolphin (*Tursiops truncatus*), and Cuvier's beaked whale (*Ziphius cavirostris*). The IMMA boundaries are defined by the 200-meter depth contour and encompass the marine environments surrounding the Ionian Islands extending to the mainland Greek coastline.

Additionally, the exploration well is located within the Southern Adriatic and northwestern Ionian Sea. The broader Southern Adriatic and Northern Ionian Sea region is identified in the IMMA e-Atlas as an Area of Interest (AoI), indicating a region under evaluation for possible future IMMA designation.

In the broader regional context, other formally designated IMMAs include the Hellenic Trench, the Gulf of Ambracia, and the Gulf of Corinth. The Hellenic Trench IMMA is located further south, at a distance of approximately 187 km from the exploration well, and serves as a critical habitat for deep-diving cetaceans. Due to historical mass stranding events temporally associated with underwater noise, it has been designated as an Area of Special Concern for Beaked Whales, with recommended precautionary measures for industrial noise-generating activities. The Gulf of Ambracia IMMA is located approximately 168 km to the east of the well, and this semi-enclosed gulf is notable for supporting a highly resident and Critically Endangered subpopulation of common bottlenose dolphins. Finally, the Gulf of Corinth IMMA is located approximately 158 km to the east/southeast of the project area, supporting mixed groups of dolphins in a semi-enclosed pelagic habitat.

#### 8.5.4.3 Cetacean Critical Habitats (CCHs) designated by ACCOBAMS

The closest Cetacean Critical Habitat (CCH) to the project area is the Sazani Island-Karaburun Peninsula, located approximately 72 km north from the exploration well. This site is identified as an area for the common dolphin (*Delphinus delphis*) and other cetaceans. The Eastern Ionian Sea and the Gulf of Corinth CCH is located approximately 158 km east/southeast from the well and is identified as an area for the common dolphin (*Delphinus delphis*) and other cetaceans. The Amvrakikos Gulf CCH is located approximately 168 km east from the well and is designated as an area for the bottlenose dolphin (*Tursiops truncatus*). The Kalamos CCH is located approximately 179 km east/southeast from the well and supports the common dolphin (*Delphinus delphis*) and other cetaceans. The Southwest Crete and the Hellenic Trench CCH is located approximately 187 km south/southeast from the well and is identified as an area for the common dolphin (*Delphinus delphis*) and other cetaceans.

#### 8.5.4.4 Important Sharks and Ray Areas (ISRAs)

The closest Important Shark and Ray Area to the project area is the Santa Maria di Leuca ISRA, located approximately 20 km west/southwest from the exploration well. The area includes complex coral habitat and functions as a reproductive area for the velvet belly lanternshark (*Etmopterus spinax*). The Otranto Channel ISRA is located approximately 50 km north/northwest from the site. The area contains deep muddy substrates dominated by the bivalve *Gryphus vitreus* and bamboo coral (*Isidella elongata*), functioning as a reproductive area for elasmobranch species. The Western Apulian Coast ISRA is located approximately 56 km northwest from the exploration well. This pelagic marine area functions as a feeding ground for the basking shark (*Cetorhinus maximus*). The Amvrakikos Gulf ISRA is located approximately 169 km east/southeast from the well.

#### 8.5.4.5 Key Biodiversity Areas (KBAs)

The closest Key Biodiversity Area to the project area is the Diapontia islands (Othonoi, Ereikousa, Mathraki) and surrounding islets KBA (2943), located approximately 40 km northeast from the exploration well. The area supports breeding seabirds and raptors. The Cape Otranto and Cape Santa Maria di Leuca coast KBA (2844) is located approximately 57 km northwest from the exploration well. It functions as a bottleneck site for migrating raptors, predominantly harriers (*Circus* spp.) and the European honey buzzard (*Pernis apivorus*). The Vlora Bay, Karaburun Peninsula and Cika mountain KBA (2908) is located approximately 80 km north from the well. The site provides habitat for breeding raptors, including the Egyptian vulture (*Neophron percnopterus*), short-toed snake eagle (*Circaetus gallicus*), golden eagle (*Aquila chrysaetos*), and Bonelli's eagle (*Hieraaetus fasciatus*). The Lagoons of Kerkyra island KBA (1169) is located approximately 80 km east from the well. The Lake Butrinti KBA (2910) is located approximately 88 km east from the well. The site contains natural tectonic lakes with reedbeds and supports species of global conservation concern such as the pygmy cormorant (*Phalacrocorax pygmeus*), ferruginous duck (*Aythya nyroca*), and greater spotted eagle (*Aquila clanga*). The Isola di Sant'Andrea KBA (2845) is located approximately 98 km northwest from the well.

#### 8.5.4.6 Important Bird Areas (IBAs)

The Important Bird Areas (IBAs) within a 100 km radius of the project area include coastal, insular, and wetland habitats across Greece, Italy, and Albania. In Greece, the closest IBA to the project area is the Diapontia Islands and surrounding islets IBA, located approximately 42 km to the northeast, which supports breeding pelagic seabirds and raptors. Further east, approximately 78 km from the exploration well, the Lagoons of Kerkyra Island IBA provides wetland habitats supporting cormorants, herons, and ducks. Along the Italian coast to the northwest, the Cape Otranto and Cape Santa Maria di Leuca coast IBA is located approximately 54 km away and functions as a bottleneck site for migrating raptors during spring, predominantly harriers (*Circus* spp.) and the European honey buzzard (*Pernis apivorus*). Further north along the Italian coastline are the Coastline of Gallipoli and Isola S. Andrea IBA (approximately 79 km away) and the Le Cesine IBA (approximately 93 km away), which feature coastal dune systems, brackish ponds, and lagoons that support wintering and migratory waterbird species. Along the Albanian coastline to the north and northeast, the Vlora Bay, Karaburun Peninsula and Cika Mountain IBA is located approximately 79 km away and supports breeding raptors, including the golden eagle (*Aquila chrysaetos*) and the Egyptian vulture (*Neophron percnopterus*). Additionally, the Lake Butrinti IBA, located approximately 88 km away, encompasses coastal tectonic lakes and reedbeds that support species such as the pygmy cormorant (*Phalacrocorax pygmeus*) and ferruginous duck (*Aythya nyroca*).

#### 8.5.4.7 Marine Protected Areas (MPAs)

The Marine Protected Areas (MPAs) within the wider region include designated sites across Greek, Italian, and Albanian waters. Within Greek waters, the closest MPA to the well is the Marine Area of the Diapontia Islands MPA, located approximately 43 km to the northeast, which encompasses shallow waters, reefs, and marine caves. Additional MPAs within the Greek Ionian include the Coastal marine zone from Kanoni to Mesongi (approximately 81 km east), the Paxoi and Antipaxoi Islands and the wider marine area MPA (approximately 93 km southeast), and the Lefkimmi salt pans MPA (approximately 97 km east). In Italian waters to the northwest, the closest site is the Costa Otranto–Santa Maria di Leuca MPA (approximately 53 km away), characterized by vegetated sea cliffs and the presence of the Mediterranean monk seal (*Monachus monachus*). Other MPAs along the Italian coastline include the Posidonieto Capo San Gregorio–Punta Ristola MPA (approximately 57 km away), the Litorale di Ugento MPA (approximately 66 km away), the Alimini MPA (approximately 69 km away), the Litorale di Gallipoli e Isola S. Andrea MPA (approximately 80 km away), the Le Cesine MPA (approximately 93 km away), and the Montagna Spaccata e Rupi di San Mauro MPA (approximately 96 km away). These sites protect coastal lagoons, endemic flora, and habitats for the loggerhead turtle (*Caretta caretta*) and bottlenose dolphin (*Tursiops truncatus*). In Albanian waters to the north, the Karaburun–Sazan Marine National Park is located approximately 79 km away and includes coralligenous communities and marine caves that harbour the short-beaked common dolphin (*Delphinus delphis*) and the date mussel (*Lithophaga lithophaga*). Further east, the Butrint National Park is located approximately 88 km away, encompassing a coastal wetland complex.

#### 8.5.4.8 Fisheries Restricted Areas (FRAs)

The closest Fisheries Restricted Area to the project area is the Deep water fisheries restricted area (1,000 m), with its nearest boundary located approximately 9 km west/southwest from the exploration well. This FRA applies directly to portions of Block 2 where water depths exceed 1,000 meters and prohibits the use of towed dredges and trawl nets to protect deep-sea benthic habitats.

The Lophelia reef off Capo Santa Maria di Leuca FRA is situated approximately 48 km west/northwest from the site. The area protects cold-water coral banks and provides habitat for priority commercial species, including the giant red shrimp (*Aristaeomorpha foliacea*), blue and red shrimp (*Aristeus antennatus*), European hake (*Merluccius merluccius*), Norway lobster (*Nephrops norvegicus*), and blackspot seabream (*Pagellus bogaraveo*).

The Otranto Channel FRA is located approximately 76 km north/northwest away from the exploration well. The area protects Vulnerable Marine Ecosystems including deep-sea sponge communities, white corals, and bamboo coral (*Isidella elongata*), while simultaneously providing habitat for dolphins, sea turtles, sea devils (*Mobula mobular*), and Cuvier's beaked whales (*Ziphius cavirostris*).

#### 8.5.4.9 Specially Protected Areas of Mediterranean Importance (SPAMIs)

The closest Specially Protected Area of Mediterranean Importance (SPAMI) to the project area is the Karaburun Sazan National Marine Park SPAMI (AL1) in Albania, located approximately 79 km north from the project site. The site encompasses marine ecosystems that support the Mediterranean monk seal (*Monachus monachus*), short-beaked common dolphin (*Delphinus delphis*), loggerhead turtle (*Caretta caretta*), date mussel (*Lithophaga lithophaga*), and purple starfish (*Ophidiaster ophidianus*).

Other SPAMIs in the broader Mediterranean basin include the Torre Guaceto Marine protected and natural reserve SPAMI (IT5) and the Porto Cesareo Marine Protected Area SPAMI (IT10) in Italy, both located to the northwest. The Torre Guaceto SPAMI protects habitats of *Posidonia oceanica*, *Cymodocea nodosa*, yellow and white sea fans (*Eunicella cavolini*, *Eunicella singularis*), bryozoans (*Sertella sp.*, *Myriapora truncata*), and red algae (*Laurencia sp.*, *Corallina elongata*). The Porto Cesareo SPAMI protects *Posidonia oceanica* meadows, coralligenous species including *Peyssonnelia*, *Agelas oroides*, *Aplysina cavernicola*, *Oscarella lobularis*, *Chondrosia reniformis*, and *Clathrina spp.*, as well as the Mediterranean monk seal (*Monachus monachus*), amberjacks (*Seriola dumerilii*), dolphinfish (*Coriphenia hippurus*), brown meagre (*Sciaena umbra*), and dusky grouper (*Epinephelus marginatus*).

#### 8.5.4.10 Ramsar sites

The closest Ramsar site to the project area is the Butrint wetland complex, located in Albania approximately 88 km east from the exploration well. The site features coastal lagoons, saltwater and freshwater marshes, reedbeds, forests, and Mediterranean scrub, supporting plant, fish, amphibian, reptile, bird, and mammal species. The Le Cesine coastal wetland Ramsar site is located in the Apulia Region of Italy, approximately 93 km northwest from the exploration well. The site features a coastal dune system and two shallow brackish ponds separated from the sea by a narrow sand barrier, supporting migratory bird populations.

#### 8.5.4.11 Emerald Network of Areas of Special Conservation Interest

The closest Emerald Network area to the project area is the Karaburun–Orikum–Dukat National Park (AL00000014), situated in Albania approximately 80 km north from the exploration well. The site encompasses marine and coastal ecosystems, including the mixed coniferous forests of Llogara, the Orikum Lagoon, and *Posidonia oceanica* marine meadows, which support endemic plant species and marine fauna. The Butrinti National Park Emerald Network area (AL00000004) is located in Albania, approximately 88 km east from the exploration well. The site constitutes a Mediterranean wetland complex comprising a lake, a lagoon, and an area of evergreen woodland. This ecological network area is utilized by wintering and migratory bird populations, including herons, egrets, and the Dalmatian pelican (*Pelecanus crispus*), and provides habitat for the Eurasian otter (*Lutra lutra*).

### 8.6 Anthropogenic environment

#### 8.6.1 Spatial planning – land uses

The overall land use and spatial planning profile of the study area is governed by a regulatory framework operating across national, regional, and local levels. For the Corfu Regional Unit, the General Framework for Spatial Planning and Sustainable Development (GFSPSD), the Regional Spatial Framework (RSF) of the Ionian Islands, and the emerging Local Urban Plans (LUPs) under L. 4759/2020 establish the spatial governance context, emphasising the preservation of the agricultural landscape, the sustainable development of tourism, and the avoidance of land use conflicts along the coastal zone. For the Thesprotia Regional Unit and the Municipality of Igoumenitsa, the RSF Epirus and the approved General Urban Plan (GUP) for Igoumenitsa provide the relevant planning framework, recognising the port of Igoumenitsa as a key development pole of the regional unit and driver of its economic identity.

The settlement and land use baseline reveals several features of relevance to the subsequent impact assessment. The Corfu Regional Unit is a densely settled island system (approximately 158 inhabitants/km<sup>2</sup>, 2021 Census) with a total permanent population of 101,600, concentrated primarily in the city of Corfu and a dispersed network of small rural settlements. The dominant land uses are olive cultivation and tourism-related coastal development, two economic activities that are entirely land-based and physically distant from the offshore drilling location. The Municipality of Igoumenitsa, with a permanent population of 25,698 (2021 Census), is characterised by a concentrated urban and port area surrounded by predominantly forested and rural hinterland. Its economic identity is closely tied to its port function, which constitutes the primary concentration of logistics and transport infrastructure in the Thesprotia Regional Unit and the entry point for the Project's Platform Supply Vessel (PSV) supply operations.

Block 2 contains no permanent settlements or land uses, and human interaction with the area is limited to maritime activities, which are addressed separately. The Project's onshore footprint is similarly limited to an operational area within the existing port zone of Igoumenitsa, entailing no change of land use, no physical displacement, and no modification of existing infrastructure.

Accordingly, the primary transmission pathways for potential social impacts from the Project are not land use change or physical displacement, but rather potential effects on maritime livelihoods, tourism perception and risk, and community-level concerns related to environmental risk. Localised economic activity may be

generated by the port-based logistics component during the drilling campaign will be examined, but it is not expected to alter the settlement structure or land use character of the municipality.

## 8.6.2 Structure and functions of the anthropogenic environment

The proposed Asopus-1 exploration well lies approximately 21.5 km (11.6 nautical miles) offshore Mathraki Island, approximately 3.2 km (1.7 nautical miles) from the Italian EEZ and in water depths of approximately 840 m. There are no islands, coastal features, or fixed subsea installations in the immediate vicinity of the well location.

The nearest onshore administrative unit is the Corfu Regional Unit, one of five regional units comprising the Ionian Islands Region. The Ionian Islands Region recorded a total permanent population of 204,532 in the 2021 Population–Housing Census.

The Corfu Regional Unit encompasses the main island of Corfu as well as the smaller islands of Paxoi, Antipaxoi, and the Diapontian Islands (Othonoi, Ereikoussa, Mathraki). Following the Kallikratis administrative reform (L.3852/2010) and subsequent adjustments under the Kleisthenis I reform (Law 4555/2018), the regional unit is currently subdivided into four municipalities. The Kallikratis reform consolidated the seven pre-existing municipalities into larger administrative entities, aiming to reduce fragmentation and improve public service delivery.

The Municipality of Igoumenitsa constitutes the principal onshore administrative area associated with the Project's maritime logistics activities, as the Port of Igoumenitsa will serve as the operational base for PSV movements supporting the offshore drilling activities. The municipality is located within the Regional Unit of Thesprotia, one of the four regional units comprising the Region of Epirus.

According to the 2021 Population–Housing Census of ELSTAT, the Regional Unit of Thesprotia recorded a permanent population of 40,804 inhabitants, representing approximately 12.8% of the total population of the Region of Epirus (319,991 inhabitants). The Municipality of Igoumenitsa recorded a permanent population of 25,698 inhabitants, corresponding to approximately 63% of the regional unit's population. Compared with the 2011 Census, the municipality experienced a marginal population decline of approximately 0.4%, while the Regional Unit of Thesprotia recorded a decrease of approximately 6.4%, broadly reflecting the wider demographic contraction observed across Epirus and Greece. The municipal unit of Igoumenitsa recorded 18,562 inhabitants at the 2021 Census, of whom 10,315 reside within the urban community boundary, establishing it as the dominant urban centre of Thesprotia but a relatively small city by national standards.

## 8.6.3 Cultural heritage

The northern Ionian Sea and the Strait of Otranto constitute a historically significant maritime corridor that has facilitated navigation, trade, and communication between the Adriatic basin, southern Italy, and the eastern Mediterranean for millennia. Archaeological evidence demonstrates the presence of extensive maritime networks operating since the Bronze Age, which intensified during the Classical, Hellenistic, and Roman periods to support the long-distance transport of amphora-borne commodities like wine and olive oil.

Recent deep-water archaeological surveys, such as those associated with the Greece-Italy POSEIDON pipeline, have fundamentally altered the understanding of regional navigation by discovering ancient shipwrecks (such as Poseidon 1 and 2) at depths exceeding 1,000 meters. These discoveries, alongside an Early Archaic shipwreck carrying Corinthian ceramics found in the Otranto Channel, provide direct evidence that ancient vessels regularly utilized offshore routes crossing the open sea west of Corfu rather than strictly navigating along the coast. Furthermore, these deep-water environments, characterized by fine sediment accumulation and low physical disturbance, provide favorable conditions for the preservation of submerged cultural heritage.

Consistent with the region's archaeological potential, an archaeological target (T057), which is interpreted as an ancient merchant shipwreck carrying transport containers, was identified at a water depth of 880.04 meters, located 8,606 meters north from the proposed well site. . Multibeam bathymetric data characterize T057 as an isolated, elongated mound rising approximately 0.6 meters above the seabed, with dimensions of 23.7 by 8.3 meters. Sub-bottom profiler data indicates the presence of buried material extending 2.20 meters below the seabed, suggesting that a substantial component of the archaeological deposit may remain concealed beneath seabed sediments.

Following the identification of the anomaly, a targeted visual inspection utilizing CathX optical imagery identified a concentration of features consistent with partially buried amphorae within the central portion of the target. The observed amphorae exhibit elongated ovoid bodies, narrow necks, and pointed bases, which are morphologically consistent with transport amphorae. Although the available imagery does not permit secure typological identification, the observable morphology has been interpreted as being broadly consistent with amphora forms associated with the Adriatic production sphere, including Lamboglia 2 and Dressel 6A types, which were widely employed between the late Hellenistic and Early Imperial periods.

The terrestrial cultural heritage baseline demonstrates that the wider study area possesses a rich cultural heritage resource reflecting continuous human occupation from prehistory to the modern era. Corfu and Thesprotia contain numerous designated archaeological sites, historic settlements, fortifications, religious monuments and architectural heritage assets, including the UNESCO World Heritage Site of the Old Town of Corfu.

## 8.7 Socio-Economic environment

### 8.7.1 Demographic data

The demographic profile of the two onshore study areas reveals two territorially and functionally distinct communities. The Corfu Regional Unit is a moderately populated island system whose effective population expands significantly during the summer tourism season, generating an annualised equivalent population increase of at least 20% and substantially higher peak-day pressures during May to October. Its age structure broadly follows the national average, with moderate demographic ageing and a youth share slightly below the national one. The seasonal character of the local economy and the coastal dependence of the dominant tourism sector means that the timing of Project activities during the summer is to be considered.

The Municipality of Igoumenitsa presents a contrasting profile: a port-oriented urban centre of 25,698 permanent residents that has proven demographically resilient relative to its wider regional unit, retaining a

younger and more nationally representative age structure than the predominantly rural and ageing Thesprotia Regional Unit. Seasonal population variation driven by tourism is modest, though transit passenger volumes through the port may generate temporary pressure during the summer season. The concentration of nearly all registered accommodation capacity within the municipality, accounting for 99.4% of the regional unit's hotel overnights, confirms Igoumenitsa's dominance as the sole urban service centre of Thesprotia.

Both study areas sit within regions experiencing long-term demographic contraction, the Ionian Islands Region at a relatively contained rate of 1.6% over the intercensal decade, the Epirus Region at a more pronounced 5.0%, against a national backdrop of sustained population decline, low fertility, and structural ageing.

These trends form the demographic context within which the Project's potential socio-economic impacts, including any temporary employment and supply chain effects at Igoumenitsa, will be assessed.

## 8.7.2 Economic activities and labor market

### 8.7.2.1 Key Economic indicators and production structure

According to the latest Annual Report of the Governor of the Bank of Greece (2025), the Greek economy maintained its positive momentum despite heightened geopolitical uncertainty and a challenging international environment. Real GDP increased by 2.1% in both 2024 and 2025, exceeding the euro area average growth rate. Economic expansion was supported primarily by investment, private consumption and net exports, while employment continued to increase, and unemployment fell to its lowest level in approximately sixteen years. At the same time, the banking sector strengthened further, with non-performing loans declining to their lowest level since Greece joined the euro area, contributing to improved financing conditions and renewed credit expansion.

According to the EC's Spring 2026 Economic Forecast, the Greek economy maintained its growth momentum in 2025, with GDP growing by 2.1% for the third consecutive year, driven by investment, private consumption, and net exports. Growth is projected to moderate to 1.8% in 2026 and 1.6% in 2027, while remaining above the EU average. Investment is expected to stay robust in 2026, supported by a record inflow of EU funds under the RRF, though the RRF wind-down in 2027 is projected to weigh on growth thereafter. On the labour market, the unemployment rate declined to the lowest recorded since 2008 (8.4% in the final quarter of 2025) and is projected to fall further to 7.9% by 2027, though long-term unemployment, at close to 5%, remains the highest in the EU. Greece is expected to maintain fiscal surpluses over the 2025–2027 period, with the public debt-to-GDP ratio projected to decline steadily towards 134% by end-2027. The outlook is subject to downside risks, including a prolonged energy price shock, which is already driving inflation from 2.9% in 2025 to a projected 3.7% in 2026, as well as potential decrease of services exports, particularly tourism, and broader global economic uncertainty.

Exploration Well Asopus 1 is associated with two principal regional economies: the Ionian Islands Region, particularly the Corfu Regional Unit, which lies closest to Block 2, and the Epirus Region, particularly the Thesprotia Regional Unit and the Igoumenitsa Municipality, which is proposed to serve as the logistics and supply base for offshore operations.

The economic characteristics of these areas differ significantly. The economy of the Ionian Islands Region is predominantly service-based and heavily dependent on tourism, which represents the principal contributor to regional GDP and employment. While the primary sector remains constrained by structural challenges such as fragmented landholdings, an ageing workforce and pressures associated with insularity and tourism development, the secondary sector is relatively limited and concentrated mainly in construction and small-scale manufacturing.

The region's strong reliance on tourism has supported economic growth and recovery in recent years but also creates vulnerability to external shocks, as demonstrated during the COVID-19 pandemic. Consequently, economic diversification, innovation and the development of higher-value productive activities remain identified regional development priorities for enhancing the long-term resilience of the regional economy. According to the ROP of Epirus 2021-2027, Epirus faces structural problems of inequalities both in relation to other regions and intra-regionally. Its productive structure includes a strong primary sector with a high share of regional GDP (8.4%), twice the national average and 5.4 times the European average. Epirus has a moderate secondary sector with a GDP (16.8%) close to the national average, while the tertiary sector is the largest in terms of GDP (74.8%) (OECD 2020). Within the Epirus Region, GDP per capita levels vary across regional units. Thesprotia consistently ranks among the highest-performing units in the region, reflecting the strategic role of the Port of Igoumenitsa, which represents a major economic asset within the region, serving as one of Greece's principal passenger and freight gateways to Italy and the wider Adriatic region.

### 8.7.2.2 Employment and unemployment

The labour market baseline indicates that the study area is situated within a national context of continued recovery following the economic crisis and the COVID-19 pandemic. Employment rates have improved and unemployment has declined substantially across Greece, although unemployment remains above the EU average and regional disparities persist.

Within the study area, the Ionian Islands Region is characterised by a high concentration of employment in trade, transport, accommodation and food service activities, reflecting the importance of tourism and related services to the regional economy. In contrast, the Epirus Region exhibits a more diversified employment structure, with significant employment in public administration, education and health, agriculture, and industry alongside service-sector activities.

At sub-regional level, both the Corfu and Thesprotia Regional Units have experienced a long-term shift in employment structure, characterised by declining agricultural employment and increasing employment in service-related sectors. Corfu displays a particularly high concentration of employment in trade, transport, accommodation and food service activities, while Thesprotia retains a more balanced sectoral profile.

From a Project perspective, the principal labour market receptors are the local workforce and businesses operating within the dominant service sectors of the study area. The Port of Igoumenitsa constitutes an important employment and logistics hub within the mainland study area, while tourism-related activities represent a significant component of economic activity in the Ionian Islands. These characteristics provide important context for the assessment of potential employment, supply chain and wider socio-economic effects associated with the Project.

### 8.7.2.3 Income and living conditions

The Ionian Islands Region, whose economy is heavily dependent on international tourism, recorded a GDP decline of approximately 20.7% between 2019 and 2020, substantially exceeding the national average contraction of 9.5%. The Corfu Regional Unit experienced a similar decline (-19.5%). By contrast, the Epirus Region recorded a smaller contraction of approximately 9.4%, broadly in line with the national average, reflecting its more diversified economic base. Thesprotia recorded a decline of approximately 11.8% over the same period.

Following the recovery of tourism and the wider economic rebound, both regions returned to a growth trajectory. By 2023, GDP in the Ionian Islands Region had exceeded its pre-pandemic level by approximately 19.7%, while GDP in Epirus exceeded the 2019 level by approximately 17.9%. Similar recovery trends were observed in the Regional Units of Corfu and Thesprotia. These trends demonstrate the resilience of the regional economies and the importance of tourism, transport and logistics activities in supporting economic growth.

Although the study area encompasses regions that are economically significant at the local and regional level, their contribution to national economic output remains relatively modest. In 2023, the Epirus Region accounted for approximately 2.0% of Greece's GDP, while the Ionian Islands Region contributed approximately 1.7%. At the regional-unit level, Corfu generated approximately 0.8% of national GDP and Thesprotia approximately 0.3%.

GDP per capita in Greece increased from €16,206 in 2015 to €21,301 in 2023. Over the same period, GDP per capita in the Ionian Islands Region increased from €14,878 to €19,502, while GDP per capita in the Corfu Regional Unit increased from €14,588 to €18,572. GDP per capita in the Epirus Region remains below the national average, although it increased steadily over the past decade from €10,950 in 2015 to €13,789 in 2023. The Thesprotia Regional Unit performs somewhat better than the regional average, supported partly by the economic contribution of the Port of Igoumenitsa, with GDP per capita increasing over the same period from €11,636 to €14,233.

Although all territorial units experienced a significant decline during the COVID-19 pandemic in 2020, reflecting the wider economic contraction, GDP per capita recovered significantly thereafter. The recovery was particularly pronounced in the Ionian Islands, reflecting the rebound of international tourism and associated service activities. Nevertheless, GDP per capita in both Corfu and the wider Ionian Islands remains below the national average, which may indicate that the strong tourism economy does not fully translate into productivity levels comparable with those of more economically diversified metropolitan regions.

## 8.8 Technical infrastructures

### 8.8.1 Social infrastructures

Healthcare infrastructure comprises a combination of primary healthcare facilities, regional hospitals and specialised referral centres. While both regions have relatively limited hospital capacity compared with more populous parts of Greece, they are supported by an extensive primary healthcare network and access to

higher-level referral hospitals, including the General Hospital of Corfu and the University Hospital of Ioannina. The Municipality of Igoumenitsa and the Regional Unit of Corfu are also served by local health centres and associated regional clinics providing primary healthcare services.

Social protection services are delivered through regional Social Welfare Centre branches and other public social care units providing residential and community-based services for children, older persons, persons with disabilities and other vulnerable groups. Public social care infrastructure is more extensive in Epirus than in the Ionian Islands, reflecting differences in regional population and service provision.

Educational infrastructure is well established throughout the study area, with comprehensive networks of kindergartens, primary schools and secondary schools across both regions. Higher education is provided by the Ionian University and the University of Ioannina, which together support undergraduate, postgraduate and doctoral education and contribute to the wider educational and research capacity of north-western Greece.

Overall, the social infrastructure baseline indicates that the study area is served by an established network of public health, social protection and educational services operating at national, regional and local levels. The scale and distribution of these services reflect the demographic characteristics and administrative organisation of the Ionian Islands and Epirus.

## 8.8.2 Transport infrastructures

### 8.8.2.1 Road network

In the Corfu Regional Unit, the road network consists of national, provincial, urban and local roads connecting Corfu Town with the main settlements, tourism areas, port facilities and Corfu International Airport. The principal road axes include National Road 24, connecting Corfu with Paleokastritsa, and National Road 25, connecting Corfu with the Achilleion area, supported by the wider island road network. Road traffic is strongly influenced by the concentration of activities around Corfu Town, the airport and the main port, as well as by seasonal tourism-related mobility during the summer period. Coastal and low-lying road sections may be affected by climate-related pressures, including flooding, sea-level rise and coastal erosion.

The Municipality of Igoumenitsa is connected to the regional and national road network of Epirus, with the Egnatia Odos motorway starting from Igoumenitsa and continuing eastwards through Thesprotia, Ioannina and Metsovo towards northern Greece. This connection gives Igoumenitsa a strategic role as the western road gateway of the Egnatia corridor, linking maritime transport from the Adriatic with the mainland road network. The local and regional road network also supports access to the Port of Igoumenitsa, surrounding settlements and coastal connections within Thesprotia. Transport infrastructure in the wider Igoumenitsa area is also relevant in the context of climate adaptation, particularly in coastal and flood-prone areas associated with the lower Kalamas River, the Kalamas Delta and the Igoumenitsa coastal zone.

A key feature of the land transportation network in the onshore facilities study area is the terminus of the Egnatia Motorway at the southern edge of the city of Igoumenitsa, where the new port is located.

This main road corridor connects to the Preveza–Igoumenitsa National Road and the Egnatia Motorway to the south, as well as to the old Igoumenitsa–Ioannina National Road to the north.

### 8.8.2.2 Air connections

The Corfu Regional Unit is served by Corfu International Airport “Ioannis Kapodistrias”, which is one of the main air transport gateways of the Ionian Islands. The airport supports domestic and international air connections and plays a central role in the accessibility of the island, particularly during the tourist season. Its proximity to the urban and coastal zone of Corfu also makes it an important transport asset from both operational and climate-resilience perspectives.

The Municipality of Igoumenitsa does not have an airport within its administrative boundaries. Air access to the wider area is provided indirectly through regional airports, primarily Ioannina Airport, while Corfu International Airport may also provide complementary access when combined with ferry connections between Corfu and Igoumenitsa. As a result, air connectivity for Igoumenitsa is secondary to its road and maritime connectivity, with the municipality’s transport role being primarily linked to the port and the Egnatia Odos corridor.

### 8.8.2.3 Port facilities

The Corfu Regional Unit includes an extensive network of port and coastal facilities serving passenger, tourism, recreational and local maritime functions. On Corfu Island, the main port facilities include the Port of Corfu, the Port of Lefkimmi and the Port of Kassiopi, while smaller facilities support local passenger movements, fishing, recreational boating and access to nearby islands and coastal destinations. The Port of Corfu is the main maritime gateway of the island, serving ferry, cruise and tourism-related traffic, while Lefkimmi provides an important connection between southern Corfu and the mainland through Igoumenitsa.

The Port of Igoumenitsa is the principal port facility of the Municipality of Igoumenitsa and one of the most important ports of western Greece. It is classified as a port of national significance and serves domestic and international passenger, vehicle and freight movements. The port supports ferry connections with Corfu, Lefkimmi, Paxoi and Patras, as well as international Adriatic ferry routes to Italy, including Ancona, Venice, Bari and Brindisi. Its direct connection to the Egnatia Odos enhances its function as a multimodal transport node linking maritime traffic with the national and trans-European road network.

### 8.8.2.4 Maritime traffic

Maritime traffic in Corfu is primarily associated with ferry connections to mainland Greece, local and inter-island passenger services, cruise calls, recreational boating and seasonal tourism-related movements. The Corfu–Igoumenitsa ferry connection is particularly important for the island’s accessibility, supporting the movement of residents, visitors, vehicles and goods between Corfu and the mainland. Maritime activity shows a strong seasonal pattern, with increased passenger and tourism-related traffic during the summer period.

In Igoumenitsa, maritime traffic is a defining component of the municipality’s transport profile. The port handles domestic ferry services to Corfu, Lefkimmi, Paxoi and other Greek destinations, together with international Adriatic routes to Italian ports. These services support passenger mobility, freight transport, Ro-Ro operations and logistics activity, reinforcing the role of Igoumenitsa as a key gateway between Greece, the Ionian Islands and the Adriatic corridor. Due to the port’s location within a coastal and flood-sensitive

area, maritime and associated port infrastructure are relevant to climate resilience, flood risk management and coastal adaptation planning.

## 8.8.3 Technical infrastructures

### 8.8.3.1 Electric Power Transmission Network

---

According to Article 2 of Law 4001/2011, the National Electricity Distribution Network (EDDIE) of the Public Power Corporation (PPC S.A.) is located within Greek territory and consists of medium-voltage (MV), low-voltage (LV) lines, electricity distribution facilities, as well as high-voltage (HV) lines and facilities that have been integrated into this network.

The backbone of the Interconnected Transmission System consists of three 400-kV double-circuit lines that transmit electricity primarily from Western Macedonia, which is the most important energy production hub in our country. Approximately 70% of the country's total electricity generation is produced in this region, which is then transmitted to the major consumption centres of Central and Southern Greece, where approximately 65% of the electricity is consumed.

The Interconnected Transmission System also includes 400-kV lines, as well as 150-kV overhead, underground, and submarine cables connecting Andros and the islands of Western Greece—Corfu, Lefkada, Kefalonia, and Zakynthos to the interconnected transmission system, as well as a 66 kV submarine interconnection between Corfu and Igoumenitsa.

The Corfu Regional Unit and the Municipality of Igoumenitsa are both served by the Hellenic Interconnected Electricity Transmission System, operated by the Independent Power Transmission Operator (ADMIE/IPTO), together with the corresponding regional electricity distribution networks.

### 8.8.3.2 Natural Gas Network

---

The Greek natural gas market is supplied primarily through Russia, Algeria, and Turkey by companies that hold a Supply License. The National Natural Gas Transmission System transports natural gas from the Greek Bulgarian and Greek Turkish borders to consumers located in mainland Greece.

The National Natural Gas Pipeline System does not pass through either the Region of Epirus or the Region of the Ionian Islands; consequently, no section of the main pipeline or its transmission branches extends into the study area.

### 8.8.3.3 Telecommunications Network

---

The Corfu Regional Unit is served by established electronic communications infrastructure, including fixed-line, mobile and broadband networks, as well as terrestrial digital broadcasting services. Telecommunications infrastructure is particularly important in the island context, supporting residential areas, public services, tourism-related activities, transport infrastructure and emergency communications. Regional planning for the Ionian Islands identifies the strengthening of high-technology information and communication infrastructure, the expansion of tele-services and the wider deployment of fibre-optic

networks as priorities for improving connectivity, addressing insularity constraints and enhancing territorial cohesion. Digital terrestrial television coverage is provided through the national Digea network, with coverage and transmitter-centre information available at settlement level.

In the Municipality of Igoumenitsa, telecommunications infrastructure forms part of the wider electronic communications network of the Region of Epirus and serves the urban area, the port zone, public services, businesses and surrounding settlements. The area is served by fixed and mobile telecommunications and internet networks, while regional development planning identifies digital connectivity, broadband infrastructure, fibre-optic networks and 5G deployment as priorities for improving regional accessibility and supporting digital transformation. These networks are considered important supporting infrastructure for the operation of the Port of Igoumenitsa, local economic activity and administrative services, and their continued upgrade is aligned with regional objectives for smart development and improved public and business services.

#### 8.8.3.4 Renewable Energy Sources

---

According to the Hellenic Statistical Authority (ELSTAT), total petroleum product consumption in Greece reached 7.03 million metric tonnes in 2024, representing a 2.8% increase compared with 2023. At regional level, Epirus accounted for approximately 4.0% of national petroleum product consumption in 2024, corresponding to an estimated 281,000 metric tonnes. This reflects the region's petroleum demand associated with road transport, heating, commercial activity, port-related operations and other local economic uses.

The Ionian Islands Region accounted for approximately 2.3% of national petroleum product consumption in 2024, corresponding to an estimated 162,000 metric tonnes. Although lower in absolute terms than Epirus, petroleum product demand in the Ionian Islands is influenced by the insular character of the region, tourism activity, maritime transport, local mobility and seasonal fluctuations in energy use. Overall, both regions represent relatively modest shares of national petroleum product consumption, with Epirus recording higher total regional demand than the Ionian Islands.

According to data from the summary fact sheet on Renewable Energy Sources (RES) and High-Efficiency Combined Heat and Power for January 2022, the following table presents the installed capacity of RES and CHP units in the Region of Epirus and in the Ionian Islands Region.

### 8.8.4 Environmental Infrastructures

#### 8.8.4.1 Water supply

---

In the Corfu Regional Unit, water supply is provided through local municipal water supply networks and associated infrastructure, including distribution pipelines, pumping stations and storage facilities. Water resource management is linked to the Corfu-Paxoi River Basin, and the reliability of water supply may be influenced by seasonal demand, drought conditions and climate-related pressure on available water resources.

In the Municipality of Igoumenitsa, water supply is provided through the municipal distribution network and associated local water infrastructure. Regional planning for Epirus identifies the modernisation of water supply networks, leakage control and water-saving measures as priorities for improving water resource efficiency and long-term system resilience.

#### 8.8.4.2 Wastewater Management

In the Corfu Regional Unit, wastewater management is supported by existing wastewater treatment infrastructure, including wastewater treatment plants serving Corfu (EL222001012), Benitses (EL222003136), Moraitika (EL222009017) and Lefkimmi (EL222008013). These facilities form part of the wider wastewater management system of the Ionian Islands Region and are considered important environmental infrastructure, particularly in coastal and tourism-intensive areas.

The city of Igoumenitsa is served by a sewerage network. Wastewater is conveyed to the Wastewater Treatment Plant (WWTP) of Igoumenitsa (EL212001012), located at the western end of the Liotrivia peninsula (as shown in the Figure below), where it undergoes secondary treatment. The Wastewater Treatment Plant of Igoumenitsa operates under the approved Environmental Terms (AEPO) of the municipal sewerage and wastewater treatment system, published in the GG in accordance with Law 4014/2011 and is the closest treatment plant to the Port of Igoumenitsa.

#### 8.8.4.3 Solid waste Management

In the Corfu Regional Unit, solid waste management is organised through regional waste infrastructure, including landfill facilities in Central and South Corfu and a recyclable materials sorting facility located within the Corfu landfill area. The regional waste management system also includes transfer and recycling infrastructure, with continued emphasis on improving waste separation, recycling and climate resilience of waste management facilities.

In the Municipality of Igoumenitsa, solid waste management forms part of the Regional Waste Management Plan for Epirus. The regional system includes waste transfer stations, treatment infrastructure for municipal solid waste serving all local authorities of the Region and planned composting infrastructure for biowaste management in the Igoumenitsa and Preveza Regional Units. Green Point infrastructure is also foreseen at municipal level, including in the main urban centres of Epirus.

### 8.9 Anthropogenic pressures on the environment

#### 8.9.1 Pressures in the Epirus Water District (EL05)

In the context of the 2nd Revision of the Epirus River Basin Management Plan (EL05), anthropogenic pressures and their impacts on each surface water body and groundwater body were identified. In accordance with Directive 2000/60/EC, anthropogenic pressures on water bodies are defined as the totality of human activities that affect or may affect water bodies in the area where they are undertaken. The categories of pollution sources are distinguished into point sources, diffuse sources, pressure from the

introduction of priority substances, water abstractions, and other types of anthropogenic pressures or pollution from other sources. Specifically, point sources of pollution include wastewater treatment plants (WWTPs), sewerage network outfalls into natural receiving waters, large hotel units, industrial facilities, livestock farming units, aquaculture and fish-farming facilities, and leakage from uncontrolled waste disposal sites and sanitary landfills. Diffuse sources of pollution encompass agricultural activities, urban wastewater not discharged to a WWTP, pastoral livestock farming, and pollution of water bodies from other sources.

The main anthropogenic pressures in the immediate and wider vicinity of the proposed shore-base facilities are primarily associated with existing port and industrial activities. Several livestock farming units are also present in the wider area, mainly to the east and southeast of the port, which may contribute diffuse loads of nutrients and organic matter through surface runoff. Aquaculture facilities and a wastewater treatment plant are located further west and represent additional pressures mainly on the coastal and marine environment. Overall, the area is already influenced by significant port and transport activity, while pressures associated with livestock farming, industrial operations, aquaculture, and wastewater treatment are more localized or occur within the wider area of influence.

## 8.9.2 Other environmental pressures in the vicinity of the project

### 8.9.2.1 Exploitation of natural resources (Offshore Oil and Gas)

Based on the review of available offshore installation data, no offshore oil and gas installations are located within the immediate area of the Asopus-1 exploration well or within a 100 km buffer. The nearest identified offshore oil and gas installation is AQUILA 2, located approximately 150 km northwest of Asopus-1 in Italian waters, which is reported as closed down. In addition, the Luna A, Luna B, and Hera Lacinia offshore installations are located approximately 150 km southwest of Asopus-1 in Italian waters and are associated with natural gas production.

### 8.9.2.2 Offshore windfarms and renewable energy

No operational offshore renewable-energy installations are present within the immediate area of the Asopus-1 well or within a 100 km buffer. The nearest identified planned offshore wind farm areas are Santa Maria di Leuca, Puglia 1, Puglia 2, and Messapia, located in Italian waters approximately 10 to 15 km from the exploration well. Additional planned offshore wind farms at greater distances include the Diapontia Islands wind farms in Greece, located approximately 40 km east of Asopus-1; the Monopoli wind farm in Italy, located approximately 60 km south; and the Odra Energia wind farm in Italy, located approximately 80 km west.

### 8.9.2.3 Fisheries and aquaculture activity

Commercial fisheries operate within the wider study area, with fishing activities conducted by both Greek and Italian fleets. The Asopus-1 exploration well is located within Geographical Sub-Area (GSA) 19 (Western Ionian Sea), while the wider Block 2 concession area spans both GSA 19 and GSA 20 (Eastern Ionian Sea). The Italian fleet operating in GSA 19 comprises vessels operating from several ports, with small-scale fishing

accounting for more than 70% of the fleet. Aquaculture facilities are confined to designated development areas on the north-eastern coast of Corfu and the Thesprotia coastline. Block 2 and the Exploration Well Asopus-1 location do not overlap with any designated aquaculture development area or existing aquaculture installation, and there is no identified direct spatial overlap with the offshore project area.

#### 8.9.2.4 Shipping and navigation

---

At the location of the Asopus-1 exploration well, atmospheric emissions are primarily associated with maritime activities, particularly international shipping and vessel movements. The overall vessel density pattern indicates that the main navigation corridors are concentrated west of Corfu and follow a northwest-southeast alignment through the central Ionian basin. The specific sea area west of Corfu encompassing the Asopus-1 well falls within a zone of relatively low vessel traffic, situated close to regional vessel transit corridors but outside the highest-density shipping routes mapped in the wider area.

#### 8.9.2.5 Military exercise areas

---

According to data provided by the Hellenic Navy Hydrographic Service, there are no permanently established military exercise areas, nor are there any temporary restricted or reserved areas currently in force, within the boundaries of Block 2 and the location of the Asopus-1 exploration well.

#### 8.9.2.6 Marine litter

---

The analysis of AUV mosaics obtained during the conduction of the LOT01 Geophysical campaign revealed a limited observed presence of marine litter in the investigated areas. In the area of the Asopus-1 well, most of the analysed stations showed no evidence of marine litter, with the exception of a localized presence of a fishing net and textile material at one station. In the vicinity of the Northern station group, three stations showed no presence of marine litter, while the remaining stations exhibited a limited contribution of items, such as a wooden object. Overall, the detected items were discontinuously and locally distributed, with no significant accumulation patterns associated with the Asopus 1 station group and Northern station group compared to the Blank and Reference stations. The observed distribution is consistent with the interpretation that the occurrence of marine litter on the seafloor is primarily controlled by local processes of transport, deposition, and retention of materials, as well as by point-source anthropogenic inputs.

### 8.10 Atmospheric environment – air quality

---

At the location of the Asopus-1 exploration well, the offshore environment is not influenced by direct terrestrial emission sources, such as residential areas, agriculture, or industrial activities. Atmospheric emissions within the offshore area are primarily associated with maritime activities, particularly international shipping and vessel movements. These activities generate emissions of sulfur oxides (SO<sub>x</sub>), nitrogen oxides (NO<sub>x</sub>), and particulate matter (PM), which may influence local atmospheric conditions and contribute to secondary aerosol formation. Accordingly, vessel traffic is considered the main anthropogenic source of temporal variability in offshore air quality.

An ambient air quality monitoring station was commissioned in 2026 at Ladochori, near the Port of Igoumenitsa, by the Ministry of Environment and Energy to support continuous monitoring of air quality conditions in the coastal area. As monitoring data from this station were not publicly available at the time of preparation of this report, the baseline characterisation presented below is based on the latest available datasets from the European Environment Agency (EEA).

For the adjacent onshore administrative areas, including the Regional Units of Corfu and Thesprotia, available 2024 spatial air quality data from the EEA indicate that recorded concentrations of monitored pollutants remain below applicable EU limit values. The baseline assessment of the monitored parameters is summarised below:

- Particulate matter (PM10 and PM2.5): Annual mean concentrations of PM10 in the Regional Units of Corfu and Thesprotia are generally below 31  $\mu\text{g}/\text{m}^3$ , remaining below the EU limit value of 40  $\mu\text{g}/\text{m}^3$ . PM2.5 concentrations are predominantly at or below 10  $\mu\text{g}/\text{m}^3$ , below the applicable EU limit value of 25  $\mu\text{g}/\text{m}^3$ .
- Gaseous pollutants ( $\text{NO}_2$ ,  $\text{NO}_x$ ,  $\text{SO}_2$ , CO and NO): Nitrogen dioxide ( $\text{NO}_2$ ) and nitrogen oxides ( $\text{NO}_x$  expressed as  $\text{NO}_2$ ) concentrations are reported at or below 10  $\mu\text{g}/\text{m}^3$ , below the respective EU limit values of 40  $\mu\text{g}/\text{m}^3$  and 30  $\mu\text{g}/\text{m}^3$ . Sulfur dioxide ( $\text{SO}_2$ ) concentrations do not exceed 5  $\mu\text{g}/\text{m}^3$ , below the EU limit value of 20  $\mu\text{g}/\text{m}^3$ . Carbon monoxide (CO) and nitrogen monoxide (NO) concentrations are also reported within the lowest available measurement ranges.
- Heavy metals and hydrocarbons: Concentrations of heavy metals and hydrocarbons associated with particulate matter remain within the lowest reported data categories. Annual mean concentrations of arsenic (As), lead (Pb), and cadmium (Cd) are below their respective EU limit values. Similarly, concentrations of benzo[a]pyrene (BaP) and benzene ( $\text{C}_6\text{H}_6$ ) comply with the applicable EU standards.

## 8.11 Acoustic environment and vibrations

The acoustic environment of the broader Ionian Sea is influenced by a combination of natural biotic and abiotic sources, including marine organisms, wind, and waves, together with significant anthropogenic activities. According to the Marine Strategy Framework Directive (MSFD) assessments for underwater noise (Descriptor 11), the wider region currently lacks established baseline levels and regulatory threshold values for the robust assessment of Good Environmental Status (GES).

Regional soundscape monitoring conducted between 2016 and 2023 across coastal areas extending from the southwestern Peloponnese to Corfu Island indicates that the area is influenced by significant anthropogenic pressures. In the North Ionian Sea, peak sound pressure levels (SPL<sub>peak</sub>) of up to 127.1 dB re 1  $\mu\text{Pa}$  were recorded, with higher levels observed in the more intensively navigated Inner Ionian Sea (129.2 dB re 1  $\mu\text{Pa}$ ). Chronic low-frequency underwater noise within the basin is primarily associated with commercial shipping and fishing vessel activity, while intermittent high-intensity noise events are typically related to military activities, active sonar use, and regional offshore exploration.

To support the oceanographic and acoustic baseline characterisation, an integrated mooring line was deployed offshore midway between Italy and Corfu for a period of 23 days, from 05.04.2026 to 27.04.2026. Data obtained from the deployed single-point current meters indicated stable local current conditions, with speeds generally below 0.10 m/s and a predominant south-southeastward flow direction. The mooring line

was also equipped with an autonomous Passive Acoustic Monitoring (PAM) system to characterise the baseline ambient soundscape and assess the temporal presence of marine mammals.

The PAM system consisted of a CO.L.MAR. GP1190 broadband hydrophone coupled with an RTSYS Sylence-LP autonomous low-power sound recorder. It was configured with a sampling rate of 256 kHz, 24-bit resolution, 15 dB gain, and a 3 Hz high-pass filter. The system operated continuously with a 100% duty cycle, generating 1,467 files of 1,200 seconds each and approximately 2 TB of raw acoustic data. After excluding the deployment and recovery periods to remove operational vessel noise, 20 days of clean baseline acoustic data were available for analysis. The results indicated an average L90 value of  $100.5 \pm 1.2$  dB re 1  $\mu$ Pa within the 63 Hz one-third octave band, which is interpreted as being consistent with a moderately trafficked shipping environment influenced by intermittent noise from commercial vessels, active sonar activities, and distant seismic operations.

Regarding offshore vibrations, naval activities can represent a potential source of underwater vibration, with weapon testing generating energy transmitted through both the water column and seabed. In general, military sonar operations are episodic, being associated mainly with training, experimentation, and system development activities. However, based on information provided by the Hellenic Navy Hydrographic Service, no permanently established military exercise areas and no temporary restricted or reserved areas currently communicated through NAVTEX broadcasts and/or Notices to Mariners are located within Block 2 or in the vicinity of the Asopus-1 Exploration Well.

## 8.12 Electromagnetic fields

Electromagnetic fields occur naturally in the marine environment, with the Earth's magnetic field being the most important natural source. Human activities introduce additional electromagnetic fields through power transmission cables, which can propagate into the marine environment and fall within the sensitivity range of many species. However, the submarine cable routes crossing the central and southern Ionian basin between the Italian and Greek coasts are telecommunication cables. Because these systems transmit data rather than heavy power, the electromagnetic fields produced in the Project area are considered likely to be negligible in comparison with power transmission cables.

The desktop spatial analysis undertaken for the Project indicates that three cable systems are located within the immediate study area and are of direct relevance to the Exploration Well Asopus-1: the planned Eagle system connecting Egypt, Albania, and Italy; the Jonah system (operational since 2012) linking Israel and Italy; and the Asia Africa Europe-1 (AAE-1) system (operational since 2017) connecting Asia, Africa, and Europe. In addition to these, the wider Ionian Sea hosts a broader network of active submarine cable systems of international significance, including the OTEGLOBE Kokkini-Bari cable (operational since 2004 with a length of 700 km), the Italy-Greece 1 (IG-1) cable, the Ionian cable, the Adria-1 cable, and the Thetis cable.

During LOT 01, utilising MBES and HISAS systems, different cables were detected within the study area, mostly exposed on the seafloor. In the south-western sector, a cluster consisting of three cables was recognised and interpreted as belonging to the AAE-1 submarine cable system. Acoustic data identified this AAE-1 cable passing at a minimum distance of 2,692 meters from the Asopus-1 exploration well. In the southernmost portion of the area, a trench excavated for cable installation extended for thousands of meters in length. Moving toward the central sector, the cable trench was no longer visible due to the presence of Mass Transport Deposit harder sediments, suggesting the presence of these hard substrates prevented

trench excavation and the cables were laid directly on the seafloor. Finally, in the northeastern part of the study area, another cable segment was identified at a distance of 6,700 meters from the planned well location. This cable appeared thin, partially buried, and showed a discontinuous path before terminating near an isolated mound.

## 8.13 Water

### 8.13.1 Management plans

#### 8.13.1.1 River Basin Management Plan (RBMP)

---

The shorebase facilities of the Project are located within the Water District of Epirus (EL05), for which a River Basin Management Plan (RBMP) has been prepared in accordance with the requirements of the Water Framework Directive (Directive 2000/60/EC), as transposed into national legislation through Law 3199/2003 and Presidential Decree 51/2007.

The 2nd Revision of the RBMP for the Epirus Water District was approved and published under Government Gazette A/71/17.05.2024. According to the RBMP, the nearest surface water bodies to the Port of Igoumenitsa are primarily coastal water bodies associated with the Kalamas River Basin District.

The Port of Igoumenitsa is directly adjacent to the coastal water body “Igoumenitsa Bay” (EL0512C0003H), which is classified as a heavily modified water body due to the presence and operation of port infrastructure. West and northwest of the port area, within the marine area between Igoumenitsa and Corfu, the coastal water body EL0512C0A02N is also identified. Further south of the wider port area, the coastal water body EL0513C0004N is present and forms part of the wider Acheron coastal system. No river or transitional water bodies are located in the immediate vicinity of the shorebase facilities.

Regarding the Asopus-1 exploration well, the offshore location lies west/southwest of the Othonoi Islands and outside the boundaries of the mapped coastal water bodies. The nearest identified surface water body is the coastal water body “Othonoi Island” (EL0534C0012N), which forms part of the Corfu–Paxoi River Basin District (EL0534).

#### 8.13.1.2 Flood Risk Management Plan (FRMP)

---

Directive 2007/60/EC (Floods Directive), which entered into force on 26 November 2007, establishes a common European framework for the assessment and management of flood risks. The Directive was transposed into Greek legislation through Joint Ministerial Decision 31822/1542/E103/2010 (Government Gazette B’ 1108/21.07.2010). Its implementation is based on the preparation of Preliminary Flood Risk Assessments, Flood Hazard Maps, Flood Risk Maps, and Flood Risk Management Plans (FRMPs) for each River Basin District, with the latter reviewed every six years in accordance with the requirements of the Directive.

Flood Hazard Maps identify areas potentially affected under different flood probability scenarios (high, medium, and low probability/extreme events), while Flood Risk Maps assess the potential consequences of

flooding on population, economic activities, infrastructure, environmental receptors, cultural heritage, and protected areas. The 1st Revision of the FRMP for the Epirus Water District was approved and published under Government Gazette B' 2775/05.06.2025.

The Asopus-1 exploration well is located outside the Areas of Potential Significant Flood Risk identified in the FRMP. The nearest designated areas are located on the Greek mainland and include the lower Kalamas River floodplain, the Acheron River floodplain, the Louros–Arta plain, and low-lying areas around the Amvrakikos Gulf. These areas are associated with major river systems and coastal plains and are spatially separated from the offshore Project area.

The shorebase facilities at the Port of Igoumenitsa, however, are located within the boundaries of the Area of Potential Significant Flood Risk designated as “Lower Reaches and Delta of the Kalamas River and the Coastal Zone of Igoumenitsa”, identified by the code EL05APSF008.

### 8.13.2 Surface water

The ecological and chemical status assessment presented below is based on the approved 2nd Revision of the River Basin Management Plan (RBMP) for the Epirus River Basin District (EL05). In accordance with Directive 2000/60/EC, the status of surface water bodies is assessed separately through evaluations of ecological status or ecological potential and chemical status, considering biological quality elements, supporting physicochemical parameters, and concentrations of priority substances.

The nearest Water Framework Directive (WFD) surface water bodies to the shorebase facilities at the Port of Igoumenitsa are coastal water bodies. The coastal water body “Igoumenitsa Bay” (EL0512C0003H), which directly encompasses the port area, is classified as having good chemical status, while its ecological potential is classified as lower than good, resulting in an overall status below good. The adjacent coastal water body EL0512C0A02N is also classified as having good chemical status, but moderate ecological status and therefore moderate overall status. Further south, the coastal water body “Epirus coasts in the Ionian Sea” (EL0513C0004N) achieves both good ecological and good chemical status.

Regarding the Asopus-1 exploration well, the nearest WFD coastal water bodies are “Othonoi Island” (EL0534C0012N) and, at greater distance, “Western and Northern Coasts of Corfu” (EL0534C0009N). Both water bodies are classified as having good ecological and good chemical status, resulting in an overall good status.

Greece implements one of the largest bathing water monitoring programmes in Europe, with more than 1,700 designated bathing waters monitored annually under the requirements of the Bathing Water Directive (Directive 2006/7/EC). According to the European Environment Agency’s European Bathing Water Quality in 2025 report, Greece continues to demonstrate high bathing water quality, with the majority of monitored sites classified as excellent quality.

In the wider area surrounding the shorebase facilities at the Port of Igoumenitsa, the nearest designated bathing waters are located along the northern and southern coastal areas of Igoumenitsa Bay. To the northwest of the port, the Drepano–Makrygiali bathing water profile is located, while to the south, within the Plataria area, designated profiles include Plataria 3, Plataria 2, and Plataria–Oikismos. Additional bathing waters in the wider coastal area include Gallikos Molos, Bella Vraka, Zavia, Megas Ammos, Agia Paraskevi, Arillas, and Karavostasi. Available monitoring results indicate that these designated bathing waters are

classified as Excellent. This classification applies to the designated bathing-water profiles and does not represent the operational waters within the port basin, where local conditions may be influenced by port operations, vessel movements, and surface-water runoff.

For the Asopus-1 exploration well, the nearest designated bathing water is located at Mathraki Island, within the Diapontia Islands, and is also classified as Excellent. No designated bathing waters are located in the immediate vicinity of the well location due to its offshore setting and distance from coastal areas.

Accordingly, designated bathing waters in the vicinity of both the shorebase facilities and the Asopus-1 exploration well represent sensitive coastal receptors, and their consideration within the impact assessment is supported by appropriate pollution prevention and emergency response measures.

### 8.13.3 Groundwater

According to the 2nd Revision of the Epirus RBMP (EL05), the shorebase facilities of the Project are located within the groundwater body EL050A070 “Filiates–Igoumenitsa System”, which forms part of the Kalamas River Basin (EL0512).

The Filiates–Igoumenitsa Groundwater System (EL050A070) is classified as having good qualitative (chemical) status and good quantitative status. Elevated concentrations of chloride (Cl) and sulphate (SO<sub>4</sub>) are attributed to the natural hydrogeochemical background, while no parameter exceedances are reported as being associated with anthropogenic pressures. The main pressures identified for this groundwater body include agricultural activities, urbanisation, livestock farming, and wastewater treatment plant operation. Localised impacts from seawater intrusion are also reported. The groundwater body is not included in the Register of Protected Areas under Article 7 of WFD.

### 8.13.4 Seawater

#### 8.13.4.1 Marine Strategy Framework Directive

Under the Marine Strategy Framework Directive (MSFD), the proposed Asopus-1 exploration well is located within the “Ionian Sea and Central Mediterranean Sea” subregion. The Greek MSFD monitoring programme uses the nearest open-sea monitoring station, “Othonoi (Ionio)”, to support the assessment of Good Environmental Status (GES) in the wider project area. The monitoring programme evaluates relevant qualitative descriptors, including biodiversity (D1), eutrophication (D5), seafloor integrity (D6), hydrographical conditions (D7), contaminants (D8), and marine litter (D10).

A review of the Water Information System for Europe (WISE/EIONET) data repository indicates that site-specific raw monitoring data for the Othonoi station are not publicly available. Therefore, the assessment relies on information available for the broader Ionian Sea/Ionian–Adriatic reporting unit. At this subregional level, the Nested Environmental Status Assessment (NEAT) tool applied by the Hellenic Centre for Marine Research (HCMR) classifies the Ionian–Adriatic area as having Good overall trophic status.

Overall, the wider Ionian Sea area has been assessed as achieving GES for the majority of assessed descriptors. National assessments indicate that environmental quality standards are generally achieved for

eutrophication (D5) and contaminants in the marine environment (D8) and seafood (D9). The region also demonstrates a decreasing trend in the introduction of new non-indigenous species (D2), while 10 out of 11 assessed commercial fish stocks (D3) are considered to achieve GES, although some assessments are based on low-confidence data. Other descriptors, including biodiversity (D1), seafloor integrity (D6), and marine litter (D10), show partial evidence of achieving GES, however, their assessment remains subject to uncertainty due to limitations in data availability and spatial coverage.

#### 8.13.4.2 Seawater Quality

##### 8.13.4.2.1 Physic-chemical characteristics of the water column (CTD profiles)

The water column investigated showed a well-developed thermo-haline stratification throughout the study area, with highly comparable conditions among the Asopus-1 group station, Northern station group, Blank stations and Reference Stations, the latter showing only local differences related to bathymetry, location and sampling period. Surface waters were characterized by temperatures of approximately 16 °C, decreasing to ~14 °C in deeper layers, while salinity increased from < 38.8 PSU in the upper water column to subsurface maxima exceeding 39.1 PSU. This vertical structure was consistent with the presence of Modified Atlantic Water (MAW) in the upper layer, underlain by Levantine Intermediate Water (LIW), while deeper waters likely reflected transitional conditions resulting from mixing between LIW and Eastern Mediterranean Deep Water (EMDW). Conductivity closely mirrored the thermo-haline structure, pH remained weakly variable (generally 8.17 – 8.29), whereas Dissolved Oxygen (DO) exhibited a marked oxycline associated with the thermo-halocline, with concentrations ranging between 3.77 and 4.87 mL L<sup>-1</sup> and saturation values consistently below 100 %, indicating slight to moderate undersaturation throughout the investigated water column. Chlorophyll fluorescence was generally low, with a Deep Chlorophyll Maximum (DCM) typically occurring between ~70 and 100 m depth and peak concentrations around 0.3 µg L<sup>-1</sup> Chl-a. Turbidity remained low across all stations, generally below 0.5 FTU, with only near-surface values occasionally exceeding 1 FTU.

##### 8.13.4.2.2 Total Suspended Solids (TSS), Total Organic Carbon (TOC) and nutrients

TSS showed limited spatial variability across all station groups, with average concentrations between 11.01 ± 2.46 mg L<sup>-1</sup> around Asopus-1 (and intermediate average values at the Blank and Reference Stations). TOC was below the analytical LoQ in all samples except Surface and Middle sampling depths at Italy Ref.

Nutrient concentrations were generally low. Ammonium (NH<sub>4</sub><sup>+</sup>) reached a maximum of 0.065 mg L<sup>-1</sup> N at Italy Ref Surface, while Nitrite (NO<sub>2</sub><sup>-</sup>) remained below the LoQ in almost all samples and never exceeded 0.003 mg L<sup>-1</sup> N. Nitrate (NO<sub>3</sub><sup>-</sup>) was detected only sporadically, with a maximum concentration of 0.510 mg L<sup>-1</sup> N at Italy Ref Surface. Orthophosphate (PO<sub>4</sub><sup>3-</sup>) reached a maximum of 0.0167 mg L<sup>-1</sup> P at D1b Surface, whereas Total Phosphorus (P-Tot) attained 90 µg L<sup>-1</sup> at D5b Surface. Comparison with the reference values adopted within the Greek MSFD implementation framework showed a limited number of exceedances for NO<sub>3</sub><sup>-</sup> and PO<sub>4</sub><sup>3-</sup>; the former exceeded the reference value only at D5b Middle and Italy Ref Surface, while the latter exceeded its reference value at D1b Surface, D7b Middle and Bottom, Kerkyra Ref Surface and Middle, and at all Sampling Depths of Italy Ref.

#### 8.13.4.2.3 Metals and metalloids

Among metals and metalloids, Cd, Cr VI, Co, Hg and Sn were consistently below the analytical LoQ, while Cr-Tot and Pb were only sporadically detected. Cu and Ni were generally low and detected in a limited number of samples, except at Italy Ref, where maxima of 30.0 and 10.0  $\mu\text{g L}^{-1}$  were recorded. As, Ba, Fe and Zn were quantifiable in all samples. As and Ba showed limited variability, ranging from 1.0 to 5.5  $\mu\text{g L}^{-1}$  and between 7.0 and 12.0  $\mu\text{g L}^{-1}$ . Greater variability characterized Fe (33 – 290  $\mu\text{g L}^{-1}$ ) and Zn (24 – 160  $\mu\text{g L}^{-1}$ ). Comparison with the AA-EQS of Directive 2013/39/EU (as applied in Greece) and the Italian SQA-MA values (D.Lgs. 172/2015) identified only limited exceedances for As, Pb and Ni. As exceeded the Italian SQA-MA of 5  $\mu\text{g L}^{-1}$  in two samples from Asopus-1 group station and five from the northern group station. Pb exceeded the applicable threshold of 1.3  $\mu\text{g L}^{-1}$  (reported for both Greek and Italian regulations) only at Italy Ref Middle and Bottom, while Ni exceeded the corresponding reference value of 8.6  $\mu\text{g L}^{-1}$  (both considered regulations) only at Italy Ref Bottom. All remaining metals complied with the applicable regulatory standards.

#### 8.13.4.2.4 Total Petroleum Hydrocarbons (TPH) and Polycyclic Aromatic Hydrocarbons (PAHs)

TPH, including both light-chain ( $C \leq 10$ ) and heavy-chain ( $C_{10} - C_{40}$ ) fractions, and all investigated PAHs, including their sum, were below the analytical LoQs at all Sampling Depths and Stations. Consequently, all hydrocarbon compounds for which regulatory reference values were available were below the applicable reference values.

### 8.14 Environmental trends (in the absence of the project)

In the absence of the Project, the environmental evolution of the study area will continue to be influenced by existing anthropogenic pressures, natural environmental variability, and broader climate change trends.

Within the offshore concession area (Block 2), the marine environment will continue to support existing maritime activities. At the Asopus-1 location, the bathyal mud seabed and associated deep-sea habitats will not be subject to drilling-related disturbance. Future changes in seabed morphology and shallow stratigraphy will continue to be governed primarily by natural sedimentary, tectonic, and gravitational mass-movement processes, while localized pressures associated with existing activities, including submarine infrastructure and bottom-contact fishing, may continue to occur.

The marine acoustic and atmospheric environments will continue to be influenced by ongoing maritime activities. International shipping and maritime transport will remain sources of atmospheric emissions, including sulfur oxides (SOx), nitrogen oxides (NOx), and particulate matter, as well as continuous low-frequency underwater noise. Commercial fishing activities by Greek and Italian fleets operating within Geographical Sub-Areas (GSA) 19 and 20 are expected to remain an existing source of pressure on pelagic and benthic ecosystems. In addition, the wider spatial planning framework identifies potential future developments in the northern Ionian Sea, including renewable energy projects such as the proposed Italian offshore wind farms located west of Asopus 1 exploration well.

The evolution of the regional environmental baseline will also be influenced by climate change trends. The Mediterranean basin is warming at a rate above the global average, with associated changes in oceanographic conditions, including seawater temperature and salinity patterns. These changes, together

with processes such as seawater acidification, may influence marine habitats, species distributions, and ecosystem functioning over time.

At the shorebase facilities at the Port of Igoumenitsa, existing port operations and associated logistics activities will continue to determine land use and environmental conditions. As the facilities are located within an already developed port environment, future environmental conditions in the area are expected to remain primarily influenced by existing operational activities and wider environmental trends. In the absence of the Project, no additional Project-related infrastructure development or operational pressures would occur, and the conditions in the vicinity of the shorebase facilities would be expected to remain broadly consistent with the current baseline.

## 8.15 Risks To human health, cultural heritage and/or the environment mainly due to accidents or disasters

### 8.15.1 General

This section presents the risks to human health, cultural heritage, and/or the environment due to accidents and disasters, in accordance with the requirements of Directive 2014/52/EU, which was transposed into Greek law through the following legislation:

- Joint Ministerial Decision (KYA) oik.5688/2018: “Amendment of the annexes of Law 4014/2011 (Government Gazette 209/A) according to Article 36A of this law, in compliance with Directive 2014/52/EU ‘amending Directive 2011/92/EU on the assessment of the effects of certain public and private projects on the environment’ of the European Parliament and of the Council of 16 April 2014” (Government Gazette 988/B/2018), and
- Joint Ministerial Decision 1915/2018: “Amendment of Ministerial Decisions No. 48963/2012 (Government Gazette B’ 2703) and No. 170225/2014 (Government Gazette B’ 135), issued under the authorization of Law 4014/2011 (Government Gazette 209/A), in compliance with Directive 2014/52/EU on the amendment of Directive 2011/92/EU concerning the assessment of the effects of certain public and private projects on the environment,” of the European Parliament and of the Council dated 16 April 2014 (Government Gazette 304/B/2018).

The key terms used in this section are defined below.

- Natural disaster: The occurrence, or probability of occurrence, of a potentially damaging natural hazard, including extreme weather events such as storms, floods, and extreme temperatures, or ground-related hazards such as subsidence, landslides, and earthquakes, within a defined time period and geographical area. According to Directive 2014/52/EU, natural disasters include floods, sea-level rise associated with climate change, and earthquakes. The United Nations defined natural disasters in 1992 as serious disruptions to the functioning of society that cause widespread human, material, or environmental losses exceeding the affected society’s ability to cope using its own resources. According to the United Nations, natural disasters are estimated to kill approximately 90,000 people and affect 160 million people worldwide each year.
- Major accident: Directive 2014/52/EU does not provide a corresponding definition of a major accident. A relevant definition is provided in Directive 2012/18/EU on the control of major-accident hazards

involving dangerous substances, where a major accident is defined as an event—such as a large release, fire, or explosion—resulting from uncontrolled developments during the operation of any establishment covered by the directive, which causes serious immediate or delayed risks to human health or the environment, inside or outside the establishment, and involves one or more dangerous substances. In general, a major accident can be considered an event that causes serious damage to human health, well-being, and/or the environment, either immediately or with a delay, such as loss of life, permanent injury, or permanent/long-term damage to environmental components that cannot be remedied with minor cleanup and restoration efforts.

- **Exposure:** People, property, systems, or other elements located within hazard zones and therefore subject to potential losses (UNISDR Terminology on Disaster Risk Reduction, United Nations, 2009).
- **Vulnerability:** The characteristics and conditions of a community, system, or asset that make it susceptible to the harmful effects of hazards (UNISDR Terminology on Disaster Risk Reduction, United Nations, 2009).
- **Risk of occurrence:** The likelihood that an impact will occur, combined with the consequences of that impact for the relevant receptor if it occurs (UNISDR Terminology on Disaster Risk Reduction, United Nations, 2009).
- **Significant impact:** An impact arising from an event that results in loss of life, permanent injury, or long-term damage to an environmental receptor.

Natural disasters may be distinguished and classified according to their causes and severity. The World Health Organization classifies them into the following categories:

- Hydrological, such as floods.
- Geophysical, including earthquakes, volcanic eruptions, and landslides.
- Meteorological, such as storms and thunderstorms.
- Climatological, such as extreme very high or very low temperatures and natural fires.
- Biological, caused by the exposure of living organisms to pathogenic microorganisms.

The size-frequency relationship describes how the potential consequences of a disaster depend on both the magnitude of the event and its frequency of occurrence. Large-scale events are typically less frequent but may have severe consequences, while more frequent events are generally of lower intensity. Average expected consequences are therefore assessed by considering both event magnitude and frequency.

In Greece, the most common natural disasters are due to earthquakes, heavy rainfall and floods, fires that can lead to deforestation of areas which, when steeply sloped, promote the occurrence of landslides, and heatwaves.

Technological disasters are primarily man-made events resulting from technological hazards that are not properly managed or from technological incidents caused by human error, equipment failure, or organisational and administrative deficiencies. They may also be triggered by natural hazards, such as earthquakes, lightning, or heavy rainfall, or by deliberate human actions. Although technological disasters are generally infrequent, they may have very serious consequences.

Depending on their intensity and extent, technological disasters may cause loss of life or injury to workers at the accident location and to populations located permanently or temporarily nearby. They may also cause property damage, disruption of social and economic life, and environmental degradation.

The usual classification of technological accidents is as follows:

- Chemical accidents at industrial facilities: occur at industrial sites (production, processing, or storage) resulting in severe environmental pollution from the release of heavy metals and toxic chemical substances.
- Accidents involving the transportation of hazardous materials: happen during the transport of dangerous goods by various means of transport (road, rail, maritime, air).
- Transportation accidents: road, rail, maritime, air. These are conventional transportation accidents, which usually result in loss of human life and injuries, but do not have significant impacts on the environment.
- Dam failure: rare events with potentially major consequences, including loss of life and significant environmental impacts.
- Nuclear accidents: usually involve the release of radioactive elements into the environment and have long-term impacts on both human health and the environment.

Although environmental disasters are not everyday events and are therefore not frequent causes of death or material damage, their potential to cause unexpected catastrophic losses makes them highly significant. Environmental disasters typically share the following characteristics:

- The source of the disastrous event is clear and produces characteristic outcomes (e.g., a flood causes deaths by drowning).
- The warning time is usually short.
- Most losses caused, whether in human lives or property, occur immediately following the event.
- The risk of exposure is largely involuntary, usually due to populations residing in hazardous areas.
- The disaster has such intensity and scale that it requires an immediate response.

This section describes potential serious accident or disaster risks in the study area arising from external factors outside the Project, in accordance with Joint Ministerial Decision 1915/2018 and taking into account the information presented in the preceding sections of Chapter 8. Based on the guidance in Directive 2014/52/EU, the main external risks to which the Project may be vulnerable are primarily natural hazards and include the following:

- Natural Disasters:
  - Flooding from inland waters,
  - Flooding from coastal waters,
  - Sea level rise,
  - Extreme weather events (windstorms, lightning, frost, hail),
  - Fires,
  - Landslides, slope failures due to flooding and/or erosion,
  - Earthquakes,

- Pandemics (e.g., COVID-19, H1N1).
- Man-made accidents / disasters:
  - Road accidents (vehicle collisions, vehicle rollovers, explosions, fires, etc.),
  - Air accidents (helicopter/aircraft crashes),
  - Technological accidents / disasters resulting from failures of existing infrastructure or other human activities (fuel stations, livestock units, photovoltaic plants, agriculture, etc.).
  - Sabotage (e.g., arson, vandalism, explosive device, use of radioactive, nuclear, biological, and chemical substances, other unlawful acts).

The “Statistical Overview of Emergency Declarations” of the General Secretariat for Civil Protection (GSCP, 2020) indicates that, during the period 2014–2020, the main categories of disastrous events resulting in emergency declarations in the Region of Epirus included extreme rainfall events, floods, and earthquakes. Within the Thesprotia Regional Unit, where the onshore Project facilities are located, these events represent the primary recorded natural hazards.

## 8.15.2 Natural disasters

### 8.15.2.1 Seismic hazard

The seismotectonic setting of the Mediterranean is controlled by the slow convergence of the African (Nubia) and Eurasian tectonic plates. The Eastern Mediterranean basin is tectonically active, driven primarily by two subduction zones: the Hellenic subduction zone located south of Greece and the Calabrian subduction zone south of Italy (Miramontes et al., 2023). These peripheral tectonic margins dictate the regional seafloor morphology and concentrate active seismogenic faults and historical earthquake epicenters.

Within this structural framework, the Apulian platform and the Ionian Sea constitute the “Ionian-Apulian microplate”, which rotates counterclockwise relative to the African plate (Gallais et al., 2011). This movement induces diffuse internal deformation across the deep Ionian basin (Gallais et al., 2011). Consequently, while the region of Western Greece and the Ionian Sea experiences frequent small to medium earthquakes alongside intermittent strong seismic events, the seismicity is spatially variable and concentrated along the subduction complexes.

At the location of the Asopus-1 exploration well, the local tectonic regime is characterized by a structurally uplifted carbonate platform environment, known as the Apulian platform. This offshore area is geographically separated from the compressive subduction zones of the Hellenic and Calabrian arcs. Based on the spatial analysis of historical seismicity catalogues (1901–2020) and the mapped active fault network provided by the Seismotectonic Atlas of Greece (NKUA), the project area is situated away from high-density earthquake epicenters and is characterized by relatively weak to moderate background seismicity. Furthermore, sub-bottom profiler and acoustic data acquired during the LOT 01 Geophysical Survey Campaign indicate that while buried fault structures with offsets of several metres are present, no corresponding fault scarps or measurable fault-related displacements were identified at the seabed within a 500-meter radius of the well location. The local seabed morphology therefore does not show evidence of recent active tectonic deformation identifiable at the survey scale.

### 8.15.2.2 Flood Risk

The Project's shorebase facilities at the Port of Igoumenitsa are located within the boundaries of the Area of Potential Significant Flood Risk (APSFR) designated as "Lower Reaches and Delta of the Kalamas River and the Coastal Zone of Igoumenitsa" (Κάτω ρους – Δέλτα π. Καλαμά και παράκτια ζώνη Ηγουμενίτσας), identified as EL05APSFR008 within the Epirus Water District (EL05). The 1st Revision of the Epirus Flood Risk Management Plan was approved and published under GG 2775/B/05.06.2025.

The APSFR EL05APSFR008 covers an area of approximately 70.5 km<sup>2</sup> and forms part of the Kalamas River Basin (EL12). It includes the downstream section of the Kalamas River, extending from the Kalamas irrigation and hydroelectric dam at Gitani to the river mouth, with a total length of approximately 27 km. The southern part of the APSFR also includes the Vlachos Stream (approximately 7.5 km), the Lakkas Stream (approximately 2.2 km), which discharge south of the Port of Igoumenitsa, and the Goura Stream (approximately 4.7 km) near Nea Selefkeia.

### 8.15.2.3 Rise of Mean Sea Level (MSL)

The Mediterranean Sea is considered sensitive to long-term climate and sea-level changes due to its semi-enclosed characteristics and geological setting (Coll et al., 2010). Future mean sea level (MSL) projections for the 21st century indicate a progressive increase under different climate change scenarios. For the Mediterranean basin, probabilistic projections estimate a median MSL rise by 2100 of approximately 54 cm under the intermediate RCP4.5 scenario and 72 cm under the high-emission RCP8.5 scenario (Kopp et al., 2014; Marcos et al., 2023).

In addition to absolute MSL changes, relative sea-level rise (RSLR) and coastal migration assessments available through the European Atlas of the Seas identify spatial differences along European coastlines, including areas affected by erosion, submergence, stability, or accretion (EMODnet Geology). These datasets support the assessment of potential climate-related pressures on coastal areas and infrastructure.

At the Asopus-1 exploration well location (Block 2), the deep offshore setting limits exposure to direct coastal effects associated with sea-level rise, such as erosion or coastal inundation. However, the Project's shorebase facilities at the Port of Igoumenitsa are located within a low-lying coastal area and may be subject to long-term climate-related pressures, including sea-level rise, coastal flooding, and erosion.

### 8.15.2.4 Tsunamis

As mentioned above, tsunami generation in the Mediterranean is primarily associated with seismic activity along the Hellenic Arc, regional tectonic structures, and submarine slope failures triggered by earthquakes or volcanic activity (Maramai et al., 2014; Lionello et al., 2023). Historical records indicate that the Hellenic Shelf has experienced 160 probable and definite tsunami events since AD 1628 (Seismotectonic Atlas of Greece v1.1, NKUA). The probability of a major tsunami originating directly within the offshore Project area is considered low based on currently available regional seismotectonic information and its distance from the main tsunamigenic sources. However, the onshore facilities at the Port of Igoumenitsa and surrounding coastal areas may be exposed to remotely generated tsunami events ("tele-tsunamis") originating from

distant seismic sources along the Hellenic Arc or from submarine landslides affecting the wider Ionian and Hellenic margins (Fischer et al., 2015; Seismotectonic Atlas of Greece v1.1, NKUA).

### 8.15.2.5 Extreme weather events

The risks associated with extreme meteorological events for the onshore facilities include storms, strong winds, and extreme temperatures. Storm events depend on local atmospheric conditions and are influenced by factors such as air mass movement, humidity, temperature variations, surface characteristics, local morphology, and drainage conditions. Floods and storms represent significant natural hazards in Europe due to their potential economic and environmental impacts, with the severity of consequences depending on the intensity and duration of the event and the characteristics of the affected area. For the study area, available meteorological records from the nearest station indicate generally moderate wind conditions, with strong wind events occurring occasionally but not frequently. Therefore, the vulnerability of the area to storm and wind-related hazards is considered to be moderate, with associated potential impacts on human health, infrastructure, cultural heritage, and the environment.

Extreme temperatures, particularly heat events, represent a potential hazard mainly for human health. However, within the study area, where dense urban development and heat-island effects are limited, vulnerability to extreme temperatures is considered low. Climate projections for the period 2031–2060 indicate that the wider onshore study area is not expected to experience a significant increase in the occurrence of very hot days ( $TX > 35^{\circ}\text{C}$ ) under either the RCP 4.5 or RCP 8.5 climate scenarios (Adaptive Greece Hub, 2026). Consequently, the associated risk from extreme temperatures to human health, cultural heritage, and the environment is considered likely to be not significant.

### 8.15.2.6 Risks of landslides / subsidence / slope failures

Gravitational mass movements, such as submarine landslides and slope failures, are significant geological hazards typically associated with steep slopes and fault scarps in the submarine environment. In the broader region of the Hellenic shelf, these mass movements affect Late Pleistocene and Holocene deposits and are primarily triggered by regional seismic activity and sediment liquefaction. Additional localized factors that may contribute to these movements include steep seabed gradients and the presence of gas within sediment pore spaces (Ferentinos et al., 2014; Fischer et al., 2015).

Based on landslide susceptibility mapping from EMODnet, seabed slope and bathymetry are the two main environmental variables controlling offshore landslide susceptibility (Innocenti et al., 2020). Slope gradient represents the dominant factor influencing landslide occurrence, contributing approximately 82% to the predictive capacity of occurrence models (Innocenti et al., 2020). While the highest susceptibility values are generally associated with steep and tectonically active regions of the Mediterranean, including the Aegean arc, the Block 2 project area is located within a zone characterized by low susceptibility values.

At the precise location of the Asopus-1 exploration well, the probability of encountering submarine landslides or active gravitational mass movements is considered low. High-resolution geophysical surveys conducted during LOT 01 within a 500 m radius of the well indicate relatively gentle seabed gradients, with an average slope of approximately  $1.3^{\circ}$ . Although localized slope increases exceeding  $10^{\circ}$  occur along the flanks of exposed harder sediments associated with the MTD, no fault scarps or active deformation features are

identified within the immediate area of the well. Furthermore, acoustic data confirm the absence of recent remobilization of the underlying MTD unit or active seabed instability. Consequently, the potential for slope instability, active subsidence, or mass failure at the Asopus-1 drilling location is considered low based on the available geophysical and bathymetric data.

The shorebase facilities of the Project are located within the EL05, for which the 1st Revision of the FRMP has been developed and approved under GG B' 2775/2025. According to the current FRMP, annual soil erosion rates within the wider study area of the shorebase facilities range from very low to low, with estimated values of 0–10 t/ha. These values indicate limited susceptibility to soil erosion under current environmental conditions.

#### 8.15.2.7 Fire risk

The occurrence and behavior of forest fires are influenced by a combination of natural, geomorphological, meteorological, and vegetation-related factors. Solar radiation, air temperature, and surface temperature affect ignition potential, while elevation influences temperature and humidity conditions that control fire spread. In addition, slope gradient affects fire propagation, as fire intensity generally increases when moving uphill due to the preheating of vegetation by rising hot air. Vegetation characteristics also play an important role, as different plant communities exhibit varying levels of flammability depending on species composition, fuel load, and moisture content.

Forest fires represent one of the most significant natural hazards affecting ecosystems, property, and human activities in Greece. Their occurrence is mainly associated with anthropogenic activities, including agricultural burning, discarded cigarettes, uncontrolled waste burning, intentional ignition, and accidental causes related to transport, industrial activities, or equipment failures.

Fire development is primarily controlled by three main factors: temperature, oxygen availability, and fuel characteristics, including fuel quantity, type, and moisture content. In Greece, forest fires occur predominantly within the Mediterranean vegetation zone, generally at elevations below 600 m, where flammable vegetation types such as pine forests, kermes oak formations, and shrublands are widespread. Although less frequent, fires may also occur at higher elevations under favorable climatic conditions.

The shorebase facilities are located within an existing port area on land classified as agricultural in the relevant mapping datasets, while areas surrounding the facilities include sections of dense natural vegetation, which may contribute to local fire susceptibility. According to the fire risk projections provided by EEA through the Adaptive Greece platform, the wider study area is classified within a medium fire risk category for the period 2031–2060 under both the RCP4.5 and RCP8.5 climate scenarios (Adaptive Greece, 2026).

### 8.15.3 Anthropogenic accidents / disasters

#### 8.15.3.1 Road transport accident risks

The risk of road accidents is associated with traffic conditions within the onshore study area, particularly around the Project's shorebase facilities, where vehicle movements increase during the summer period. The

local road network is generally in good condition; therefore, the likelihood of a serious road accident is considered relatively low and is primarily influenced by driver behavior, traffic intensity, and compliance with road safety measures.

### 8.15.3.2 Risks of accidents from maritime transport

Maritime transport is of strategic importance to both national and EU economies, supporting international trade, connectivity between regions, and the movement of passengers and goods. Shipping operations are regulated through harmonized national legislation based on international conventions and resolutions adopted by the International Maritime Organization (IMO). In recent years, IMO has introduced a range of measures aimed at preventing marine accidents, reducing their consequences, and improving safety standards in international maritime transport.

According to IMO Resolution A.849 of 27 November 1997, which adopted the Code for the Investigation of Marine Casualties and Incidents (Casualty Investigation Code), a marine casualty is defined as any incident or sequence of incidents at sea resulting in loss of life, loss or damage to a vessel, grounding, collision, loss of manoeuvrability, damage to marine infrastructure, severe environmental damage, or the potential to cause such impacts (IMO, 2008).

The level of maritime safety within EU waters remains high. However, according to the Annual Overview of Marine Casualties and Incidents 2025 published by the European Maritime Safety Agency (EMSA), 2,659 marine casualties and incidents were reported in 2024. This represents a reduction compared with 2023, when 2,709 occurrences were recorded, but a slight increase compared with 2022, when 2,635 occurrences were reported (EMSA, 2025). During the period 2015–2024, a total of 26,751 marine casualties and incidents were reported, corresponding to an annual average of approximately 2,675 events. Of these, 53.4% were classified as less serious casualties, 28.4% as serious casualties, 2.7% as very serious casualties, and 15.5% as marine incidents (EMSA, 2025).

The main risks associated with maritime transport include vessel collisions and allisions, particularly within established shipping routes or areas where vessels with restricted manoeuvrability, such as drilling or seismic vessels, operate in proximity to cargo vessels, tankers, passenger vessels, and fishing vessels. According to EMSA (2025), collisions accounted for approximately 20.5% of ship occurrences and represented a significant contributor to fatalities and injuries. Other relevant risks include accidental releases or discharges of hazardous and non-hazardous substances, including chemicals, bilge water, sewage, solid waste, and operational residues, which may affect seawater quality and marine ecosystems.

Additional risks are associated with loss of vessel control or manoeuvrability due to propulsion failure, steering failure, electrical power loss, or machinery malfunction. Loss of propulsion was the most frequently reported ship casualty event during 2015–2024, accounting for approximately 22% of occurrences (EMSA, 2025). Grounding or stranding may occur due to navigational errors, adverse weather conditions, or loss of propulsion or steering capability. Contact incidents involving fixed or floating objects, including port structures, breakwaters, buoys, offshore installations, floating cargo, or other obstacles, represent another significant risk category and accounted for approximately 14.6% of ship occurrences (EMSA, 2025). Fire and explosion events, associated with fuel, machinery spaces, electrical systems, cargoes, or other flammable substances, also represent potential maritime hazards.

The potential consequences of maritime accidents include fatalities and injuries affecting crew, passengers, and third parties; damage to or loss of vessels, including immobilization, abandonment, loss of seaworthiness, and the requirement for towing, emergency assistance, or search and rescue operations. Environmental consequences may include oil spills involving marine fuels, bunkers, lubricants, hydraulic fluids, or oil cargo, as well as the release of ship-generated wastes, cargo residues, hazardous substances, chemicals, and other dangerous materials. Such events may result in air and marine pollution, affecting seawater quality, coastal areas, marine habitats, and sensitive biological receptors. Maritime accidents may also cause damage to other vessels, port infrastructure, offshore installations, and other assets, while disrupting navigation, port operations, and wider maritime activities.

#### 8.15.3.3 sabotage, vandalism, and other illegal acts

---

Sabotage, including acts of vandalism, arson, or other intentional damage, represents a potential cause of accidents or emergency events within the study area. However, no such incidents have been recorded to date within the study area, and the likelihood of occurrence is considered very low, taking into account the offshore location of the Project and the security measures and operational procedures expected to be implemented during Project.

## 9 Quantitative risk assessment

---

### 9.1 Introduction

#### 9.1.1 Background

---

The background of the project is defined in earlier chapters of the present ESIA. In summary, the operations include the drilling of a single offshore exploration well, named Asopus-1, in Block 2 of the Ionian Sea, offshore western Greece, in 2027.

The objective of this proposed activity is to evaluate subsurface geological formations and assess the potential presence of hydrocarbons. The well will be drilled using a mobile offshore drilling unit (MODU), specifically the Stena DrillMAX drillship, which is purpose-built for deep-water drilling operations.

The proposed activity is temporary and limited in scope, comprising the drilling, evaluation, and subsequent plugging and abandonment of the exploration well. No oil or gas production or well testing is planned as part of this project. If hydrocarbons are identified, any further appraisal or development activities would be subject to separate permitting and environmental assessment processes.

The primary drilling activity, including well construction, formation evaluation, and plugging and abandonment, will take place offshore. The well will be drilled from the Stena DrillMAX drillship through the seabed to the target formations and will be used solely for exploration and data acquisition purposes. Well construction and abandonment will be carried out in accordance with established offshore practices to ensure well integrity and prevent unplanned releases to the marine environment.

The operational area lies approximately 3.2 km (1.7 nautical miles) from the Italian EEZ and at a water depth of ~840 m. There are no islands, coastal features, or fixed subsea installations in the immediate vicinity of the well location.

The offshore operation will be supported by routine marine and aviation logistics, including helicopter operations from Corfu Airport and the use of platform supply vessels (PSVs) operating along established navigation routes between the drillship and an existing onshore supply base at the port of Igoumenitsa. These support activities do not require new construction or modification of coastal or onshore infrastructure.

#### 9.1.2 Purpose, objectives and scope

---

This section of the Environmental and Social Impact Assessment (ESIA) summarises the Quantitative Risk Assessment (QRA) studies' process performed to date in order to determine the risk to personnel associated with the proposed exploration operations.

This document identifies the applicable Major Accident Hazards (MAH) associated with using the Stena DrillMAX MODU for the proposed Asopus-1 project exploratory drilling activities.

The boundaries of the QRA/RoMH scope are as follows:

- Identification of MAHs associated with the DrillMAX MODU's activities for the Asopus-1 project.

- Assessment of risks associated with the following:
  - Blowouts
  - Fires, explosions, and toxic releases
  - Marine events
  - Other Hazards

In addition, the following are covered in the report:

- Assessment of the identified hazards against the risk acceptance criteria
- Highlighting the uncertainties and limitations in QRA
- Recommendations based on review of the existing DrillMAX QRA

For completeness, calculated IRPA levels for worker groups are presented and discussed in this report even though they have no direct relationship to the potential environmental impact of the described facilities. The safety of employed staff working offshore clearly influences the socio-economic wellbeing of the wider project area.

The purpose of the QRA is to provide a numerical estimate of the level of risk to people, associated with identified and defined Major Accidents. Risk is normally presented as IRPA (Individual Risk Per Annum – the chance each worker has of suffering a fatal accident per year of work) and PLL (Potential Loss of Life: the number of staff that might be killed in a defined period). QRA provides a means to compare the derived risk levels against industry accepted tolerability criteria and also provides a baseline against which potential risk reduction measures can be assessed.

Whilst the primary objective of the QRA is to assess risk to personnel, the assessment also identifies major accident scenarios with the potential to affect the environment. Conservative blowout scenarios from the existing Stena DrillMAX QRA are retained for personnel-risk assessment purposes. Following incorporation of the project-specific K-BOS E-SID barrier, however, a sustained uncontrolled subsea blowout is not adopted as the representative environmental release scenario for the ESIA. The representative environmental scenario is the instantaneous loss of 350 m<sup>3</sup> of MGO from a PSV fuel tank, as assessed in the oil spill modelling (Section 9.7).

No QRA was undertaken for the onshore support and logistics facilities as part of this chapter; the environmental and social risks associated with those activities are assessed in the relevant ESIA sections.

The chapter also presents the oil spill modelling undertaken for the representative environmental release scenario: an instantaneous loss of 350 m<sup>3</sup> of Marine Gas Oil from a fuel tank on board a Platform Supply Vessel supporting the drilling campaign. The assessment considers the unmitigated transport, weathering and fate of the released MGO at the sea surface, within the water column and at the shoreline.

### 9.1.3 Methodology and approach

The existing Stena DrillMAX QRA documentation has been used as the basis for identifying and assessing the major accident hazards (MAH) to personnel associated with drilling the Asopus-1 exploration well and for evaluating the calculated risks against the applicable risk acceptance criteria.

This approach ensures the applicable aspects of the analysis completed as part of the DrillMAX QRA are tailored to the specifics of the Asopus-1 project.

The environmental consequences of the representative accidental release scenario were assessed separately using stochastic and deterministic oil spill modelling. The representative scenario is the instantaneous loss of 350 m<sup>3</sup> of MGO from a PSV fuel tank. Season 1 stochastic results provide the primary risk-envelope basis for the proposed drilling period, while the Season 2 deterministic simulations are retained as supplementary sensitivity cases.

#### 9.1.4 Legislative and regulatory requirements

This QRA estimates the numerical level of risk associated with major accidents. Directive 2013/30/EU on the safety of offshore oil and gas operations was transposed into Greek law through Law 4409/2016. Major accidents are defined in Article 2 of Directive 2013/30/EU and the corresponding provisions of Law 4409/2016 as follows:

- a. *an incident involving an explosion, fire, loss of well control, or release of oil, gas or dangerous substances involving, or with a significant potential to cause, fatalities or serious personal injury;*
- b. *an incident leading to serious damage to the installation or connected infrastructure involving, or with a significant potential to cause, fatalities or serious personal injury;*
- c. *any other incident leading to fatalities or serious injury to five or more persons who are on the offshore installation where the source of danger occurs or who are engaged in an offshore oil and gas operation in connection with the installation or connected infrastructure; or*
- d. *any major environmental incident resulting from incidents referred to in points (a), (b) and (c).*
- e. *for the purposes of determining whether an incident constitutes a major accident under points (a), (b) or (d), an installation that is normally unattended shall be considered attended.*

The assessment has been prepared with reference to the applicable requirements of Law 4409/2016 and HEREMA guidance documents. This QRA assessment has been prepared to address the relevant requirements, including clauses 1 and 4 as below:

1. Operators shall ensure that all suitable measures are taken to prevent major accidents in offshore hydrocarbons operations.
4. Operators shall ensure that offshore hydrocarbons operations are carried out on the basis of systematic risk management so that the residual risks of major accidents to persons, the environment and offshore installations are tolerable.

It is noted that the Report of Major Hazards, (RoMH) of Stena DRILLMAX, has been submitted to HEREMA (Ref. Number: 36452/14.07.2026) and is currently under review.

This chapter presents the project-specific QRA conclusions and the results of the oil spill modelling undertaken to support the ESIA, having regard to the applicable SEA requirements and relevant legislation.

## 9.1.5 Risk acceptance criteria

The Risk Acceptance Criteria (RAC) have been established accordance with the HEREMA ALARP Guidance, the existing Stena DrillMAX QRA framework, and applicable international offshore risk management practices.

The regulations define a safety level for people and assets and require RAC to reflect the safety objectives and distinctive characteristics of the activities. Other factors considered in the formulation of the RAC for the MODU vessel include:

- recognised international standards for the activity.
- requirements regarding risk-reducing measures.
- knowledge of accidental events and their effects.
- experience from own and corresponding activities.

The RAC for the Stena DrillMAX are consequently established for the following,

- Personnel Risk
- Main safety functions (MSFs)

### 9.1.5.1 Personnel Risk

The acceptance criteria established for personnel risk relate to the following risk indicators, consistent with the existing Stena DrillMAX Safety Case and QRA methodology:

- Fatal Accident Rate (FAR = fatalities per  $10^8$  exposed hours)
- Individual Risk Per Annum (IRPA = risk of death for a person in one year)

The mean individual risk, expressed by the Fatality Accident Rate (FAR), shall meet the following quantitative acceptance criteria, as adopted in the existing Stena DrillMAX QRA framework.

$$\text{FAR} \leq 10$$

FAR is an indication of the individual risks for workers within a particular group. It is the number of fatalities per 108 hours of exposure. FAR is typically in the range of 1-30. Based on the ALARP principle, the tolerability of the acceptance criteria is shown in Figure 9-1.

Figure 9-1: Risk criteria for FAR

The Risk Tolerability Criteria (RTC) for the Individual Risk have been adopted from the HEREMA ALARP Guidance, as shown in Table 9-1 below.

**Table 9-1: Individual Risk Tolerability Limits for Workers**

| TOLERABILITY LIMIT (RISK OF FATALITY PER YEAR) |           |
|------------------------------------------------|-----------|
| Upper                                          | $10^{-3}$ |
| Lower                                          | $10^{-6}$ |

The risk for the most exposed worker group, expressed by the Individual Risk Per Annum (IRPA), shall meet the following quantitative acceptance criteria,

$$\text{IRPA} \leq 1 \times 10^{-3}$$

Based on the ALARP principle, the following assessments are made related to the IRPA values for the worker groups, as shown in Figure 9-2 below.

**Figure 9-2: Risk Criteria for IRPA**

For the FAR and the IRPA criteria, the following main principles apply:

- Personnel exposure applies to the total period of offshore stay.
- Risk by ordinary transportation to/from the facility is included (helicopter).
- Occupational risk is included.
- The criteria apply as the mean for a 12-month period (adjusted for 70 days to represent the duration of the drilling campaign) with the highest risk.
- The mean value is to be calculated for all personnel onboard the drillship and over the entire operating period

The worker groups on the drillship have been categorised as,

- Operational (personnel in hazardous locations such as the drill floor, mud areas, pipe deck, etc.)
- Maintenance (workshop/ deck areas)
- Administrative (personnel mainly in accommodation areas)

### 9.1.5.2 Loss of Main Safety Functions

The main safety functions to be maintained in the event of an accident are as follows,

- **Escape Routes:** At least one escape route from any area outside the area initially exposed where personnel may be located shall be maintained until escape to safe areas on the vessel and evacuation of the vessel has been completed
- **Evacuation Systems:** The evacuation means shall be intact until the evacuation of the vessel has been completed
- **Structural Integrity:** The structural integrity of the primary load-carrying structure shall be maintained until evacuation of the vessel has been completed
- **Temporary Refuge (TR) / Living Quarters (LQ)** (includes the Central Control Room (CCR) on the Bridge and the DP Backup Room).

As per NORSOK Z-013, *"The frequency for impairment of any of the main safety functions shall not exceed 1.0E-04 per year for each accidental load. The total impairment frequency for each safety function, including all accidental loads, shall not exceed 5.0E-04 per year."*

Below these impairment frequencies, the risk shall be reduced in accordance with the ALARP principle. These criteria are applied to this study.

### 9.1.6 Main conclusions

The calculated Individual Risk Per Annum (IRPA) values are:

- Operational worker group      4.50E-05 per year
- Maintenance worker group    4.47E-05 per year
- Accommodation worker group      2.59E-05 per year.

The maximum calculated IRPA is 4.50E-05 per year, which is below the HEREMA upper tolerability limit of 1.0E-03 per year. The individual risk acceptance criterion is therefore satisfied.

The total Potential Loss of Life (PLL) is calculated to be 5.93E-03 fatalities per year. The principal contributors to personnel risk are helicopter transportation, occupational accidents and marine events. Blowouts, well releases, fires, explosions and toxic releases make a comparatively small contribution to the quantified overall risk.

Excluding helicopter transportation, the facility-related Fatal Accident Rate (FAR) is 2.16 fatalities per 10<sup>8</sup> exposed hours, which is below the Stena DrillMAX generic QRA FAR of 2.35 and the project acceptance criterion of 10 fatalities per 10<sup>8</sup> exposed hours. The facility-related FAR acceptance criterion is therefore satisfied.

Helicopter transportation risk has been assessed separately using actual flight-exposure hours, resulting in a FAR of 416 fatalities per 10<sup>8</sup> flight-exposure hours. Because this value is normalised against actual flight hours rather than the total offshore exposure period, it is not directly comparable with the facility-related FAR acceptance criterion. Helicopter transportation risk is included in the IRPA and PLL results.

The personnel-risk results reflect the POB, worker-group distribution, helicopter movements and campaign-duration assumptions adopted in the QRA. These inputs shall be verified against the final campaign manning, and logistics plans before operations commence, and the affected results reviewed if material differences are identified.

The calculated annual Main Safety Function impairment frequencies are:

- Escape routes: 8.99E-06 per year;
- Evacuation systems: 9.00E-06 per year;
- Structural integrity: 8.95E-06 per year; and
- Temporary Refuge: 1.05E-06 per year.

All calculated Main Safety Function impairment frequencies are below the applicable acceptance criteria of 1.0E-04 per year for each individual accidental load and 5.0E-04 per year in total for each safety function.

### **Project Specific Risk Reduction**

For the Asopus-1 campaign, Energean will deploy the K-BOS Emergency Shut-In Device (E-SID) as a pre-positioned subsea shut-in device installed between the wellhead and the Stena DrillMAX BOP stack. The E-SID provides an additional, independently actuated shear-and-seal capability at the wellhead.

The combined BOP and E-SID configuration reduces the estimated probability of an uncontrolled blowout to approximately  $2.08 \times 10^{-8}$  per well. On this basis, a sustained uncontrolled subsea blowout is not adopted as the representative loss-of-containment scenario for the Asopus-1 campaign. Deployment of the pre-positioned E-SID therefore provides a material project-specific risk reduction and supports the demonstration that well-control risks have been reduced to ALARP. This conclusion does not remove the requirement to maintain contingency source-control arrangements, including BOP intervention, well capping, containment and relief-well planning, for emergency preparedness purposes.

Accordingly, the sustained uncontrolled subsea blowout is not adopted as the representative environmental release scenario for the ESIA. The representative scenario is an instantaneous loss of 350 m<sup>3</sup> of Marine Gas Oil from a fuel tank onboard a Platform Supply Vessel supporting the drilling campaign.

Season 1, covering October to March and encompassing the proposed February/March drilling period, provides the primary stochastic risk-envelope basis for the ESIA. Under Season 1 conditions, the highest modelled shoreline-contact probability is associated with Italy, at approximately 5%, with a minimum shoreline-arrival time of approximately 2.8 days. These results represent unmitigated spill behaviour in the absence of oil-spill response measures.

The deterministic simulations were selected from the Season 2 stochastic simulation set and are retained as supplementary sensitivity cases; they are not representative deterministic simulations of the proposed February/March drilling period.

### **Comparative Analysis Results**

The Asopus-1 results have been compared with the existing Stena DrillMAX QRA base case. The comparison indicates:

- an operational IRPA approximately 75% lower than the reference case;
- a PLL approximately 89% lower than the reference case; and

- a Temporary Refuge impairment frequency approximately 84% lower than the reference case.

These differences primarily reflect the reduced operating scope and exposure period of the single-well Asopus-1 campaign. The comparison is therefore a sensitivity assessment rather than a like-for-like comparison between identical drilling programmes. The comparison also reflects the project-specific personnel and exposure assumptions adopted in the QRA.

The QRA/RoMH concludes that the MAHs associated with the Asopus-1 campaign have been identified and assessed. The calculated IRPA, facility-related FAR, and Main Safety Function impairment frequencies meet the applicable risk acceptance criteria. Together with the additional protection provided by the K-BOS E-SID, and subject to implementation and maintenance of the prevention, control and mitigation measures credited in the assessment, the results support the conclusion that the identified major accident risks have been reduced to ALARP.

The following sections present the assessment basis, methodology, results, and supporting information that lead to these conclusions.

## 9.2 Facilities and operations review

### 9.2.1 Installation description

The MODU to be used for this exploratory drilling is the Stena DrillMAX, a dual-mast, Dynamically Positioned (DP), harsh-environment, ultra-deepwater drillship, designed and certified for year-round worldwide operations. This MODU vessel was built by Samsung Heavy Industries (SHI) and commenced operations in December 2007. The MODU facility layout and General Arrangement drawings are shown in Figure 9-3 and Figure 9-4.

Figure 9-3: MODU Facility Layout

**Figure 9-4: MODU General Arrangement**

The DP Class 3 vessel has a double-hull design. The accommodation unit and helideck are situated at the forward end of the vessel. The dual hoisting towers and enclosed moonpool are situated in the midships section, with the mud processing module forward of the moonpool. The pipe deck is located on top of the mud processing module. Riser storage is to the aft of midships. A stand-building tower is located midship on the starboard side, and stands of drill pipe and casing are racked in a setback area recessed into the hull. X-tree and BOP handling areas are located forward and aft of the moonpool, respectively.

The well test area is situated to the aft of the drillship, between the engine casing and the Riser Storage Bay, is prepared to support a temporary well test package to be provided and operated by a third party. A burner boom is located aft starboard for the disposal of well-test fluids. No well testing is planned as part of the Asopus-1 exploration well programme.

Six engines / generators are arranged in three engine rooms (two engines in each room) located below the main deck aft. Each generator produces up to 7.4 MW of electrical power. The generators are connected to three 11kV switchboards from where power is distributed to all consumers onboard. All six engines are classified as emergency generators. Motive power for the drillship is provided by 6 thrusters, 3 located aft and 3 forward. The vessel is equipped with a Kongsberg Maritime Automation System (IAS), a distributed monitoring and control system built for marine and offshore applications. The IAS covers all important functions onboard, including:

- Power management
- Auxiliary machinery control
- Ballast/bunkering monitoring and control
- Fire and Gas

The IAS operating stations are in the following locations:

- Main Control Room (Forward Bridge) – 4 stations
- Engine Control Room – 2 stations
- Navigation Equipment Room – 1 station

Accommodation for 180 persons is provided in one and two-man cabins. Contained within the accommodation block are the bridge, back-up DP room, meeting rooms, offices, hospital, galley, provisions store, recreation rooms, laundry, and the mess room. The accommodation block is the designated Temporary Refuge. The vessel is equipped with six free-fall lifeboats, two each located forward on the port and starboard sides, and two at the aft end of the vessel. Port and starboard escape tunnels beneath the main deck and primary escape routes on the upper decks lead to the accommodation and lifeboat stations.

## 9.2.2 Facility design and layout

The Stena DrillMAX has been built to Det Norske Veritas (DNV) Rules for the Classification of Offshore Drilling and support units. The full class notation is:

+1A1 Ship-shaped Drilling unit(N), Abate(P), BIS, Crane-offshore, Cyber secure (Essential, +), DRILL (N, MPD), DYNPOS(AUTRO), EO, F(A, M), HELDK(S, H), Recyclable, UKVS

The Stena DrillMAX is registered in Aberdeen, UK

The main dimensions and details of the MODU are shown in Table 9-2 below,

**Table 9-2: Module Main Dimensions Details**

| DIMENSION                         | IMPERIAL      | METRIC          |
|-----------------------------------|---------------|-----------------|
| Length                            | 748.03 ft     | 228.3 m         |
| Breadth mid                       | 137.80 ft     | 42.0 m          |
| Depth mid                         | 62.34 ft      | 19.0 m          |
| Moon pool                         | 84 ft x 41 ft | 25.6 m x 12.5 m |
| Transit draught mid               | 27.88 ft      | 8.5 m           |
| Transit draught (Inc thruster)    | 46.92 ft      | 14.3 m          |
| Operations draught                | 39.37 ft      | 12.0 m          |
| Survival draught                  | 39.27 ft      | 12.0 m          |
| Operations draught (Inc thruster) | 58.39 ft      | 17.80 m         |
| Displacement                      | 105,822 St    | 96,000 mt       |
| Variable Deck Load                | 16,535 St     | 15,000 mt       |
| Transit speed                     | 12.0 kts      | 12.0 kts        |

The storage capacities associated with this MODU are shown in Table 9-3 below,

**Table 9-3: MODU Storage Capacity Details**

| MATERIAL            | CAPACITY (METRIC)     |
|---------------------|-----------------------|
| Fuel oil            | 10,805 m <sup>3</sup> |
| Drill water         | 4,000 m <sup>3</sup>  |
| Potable water       | 2,000 m <sup>3</sup>  |
| Brine               | 500 m <sup>3</sup>    |
| Base oil            | 500 m <sup>3</sup>    |
| Liquid mud (active) | 800 m <sup>3</sup>    |

| MATERIAL              | CAPACITY (METRIC)    |
|-----------------------|----------------------|
| Liquid mud (Storage)  | 2,345 m <sup>3</sup> |
| Bulk Barite/Bentonite | 400 m <sup>3</sup>   |
| Bulk cement           | 400 m <sup>3</sup>   |
| Sack Material         | 7,500 sacks          |

### 9.2.3 Operational modes and activities

The scope of the major accident hazard risk analysis covers all rig areas and operations associated with the Asopus-1 campaign, including:

- Exploration drilling
- Completion activities, not applicable for Asopus-1.
- Helicopter operations
- Marine operations
- Diving operations within the 500m zone, not applicable for Asopus-1.

### 9.2.4 Analytical premises and assumptions

#### 9.2.4.1 Environmental conditions

The vessel is designed for unrestricted worldwide operation.

During drilling operations, the vessel will normally maintain a heading such that the vessel's forward is upwind (approximately  $\pm 20$  degrees).

#### 9.2.4.2 Personnel on Board (PoB)

The assessment is based on the maximum POB of 60 (as per the input from drilling and exploration for the ESIA report), which consist of,

- Operational (drill floor/mud areas/pipe deck) - 25
- Maintenance (workshops/deck areas) - 25
- Accommodation - 10

As mentioned, these inputs shall be verified against the final campaign manning and logistics plans before operations commence, and the affected results reviewed if material differences are identified, as it is possible that total POB can reach up to 180.

## 9.3 Risk assessment methodology

### 9.3.1 Major Accident Hazard (MAH) definition

The concept of a Major Accident Hazard (MAH) adopted for this assessment is consistent with HEREMA guidance and aligned with the approach used in the Stena DrillMAX Safety Case, which was developed in accordance with the UK Offshore Installations (Offshore Safety Directive) Regulations 2015, which notes:

*(a) an event involving a fire, explosion, loss of well control or the release of a dangerous substance causing, or with a significant potential to cause, death or serious personal injury to persons on the installation or engaged in an activity on or in connection with it.*

*(b) an event involving major damage to the structure of the installation or plant affixed to it or any loss in the stability of the installation causing or with a significant potential to cause, death or serious personal injury to persons on the installation or engaged in an activity on or in connection with it*

*(c) the failure of life support systems for diving operations in connection with the installation, the detachment of a diving bell used for such operations or the mapping of a diver in a diving bell or other subsea chamber used for such operations*

*(d) any other event arising from a work activity involving death or serious personal injury to five or more persons on the installation or engaged in an activity on or in connection with it or*

*(e) any major environmental incident resulting from any event referred to in paragraph (a), (b) or (d)*

The definition of 'major accident' lists types of events involving, or with the potential for, serious injury or loss of life. In compliance with the relevant HEREMA guidance, all the following have been covered in this assessment,

- All credible hazards with the potential to cause a major accident as defined have been identified.
- The risks have been evaluated.
- Measures taken to control those risks to ensure compliance with the statutory provisions.

### 9.3.2 Risk Assessment process

The key activities carried out in the risk assessment process are as follows,

- Identification of events developing Major Accident Hazards (MAH).
- Assessing the frequency or likelihood of the MAHs, based on the identified events.
- Assessing the consequences of the MAHs related to people and the surrounding environment.
- Combining the MAH's frequencies and consequences to find the numerical levels of risk.
- Assessing the calculated risk level against the risk tolerability criteria
- Develop the required risk management strategies based on the calculated risk level.

### 9.3.3 Hazard identification methodology

Identifying potential hazards on the MODU during drilling operations evolved based on the concept, design, and construction phases of the DrillMAX. A systematic review was carried out by Stena Drilling Limited (SDL) during each phase by a multi-disciplinary brainstorming team with relevant knowledge, experience, and qualifications. The Stena DrillMAX team identified the complete range of major hazards associated with the drillship and its operations. Hence, the Hazard Register developed by SDL for the DrillMAX MODU, together with risk categorisation for personnel and the environment, has been used as the basis for identifying the hazards applicable to the Asopus-1 project.

The identified MAHs are listed below:

1. Blowout and Well Releases
2. Fire, Explosion related to Well Operations
3. Release of Toxic or Other Hazardous Material
4. Fire and Explosion in Other Areas
5. Pressure Vessel Failure
6. Marine Accidents
7. Dropped Objects
8. Helicopter Accident
9. Spills to Sea

### 9.3.4 Risk classification methodology

The SDL Risk Classification Matrix was used for the initial screening of hazards and qualitative assessment of risks. The Risk Classification Matrix used in this assessment is shown in Figure 9-5 below.

|   | Consequences                        |                                                    |                                                            |                        |                                  | Likelihood                      |                           |                              |                                              |                                                      |
|---|-------------------------------------|----------------------------------------------------|------------------------------------------------------------|------------------------|----------------------------------|---------------------------------|---------------------------|------------------------------|----------------------------------------------|------------------------------------------------------|
|   | Personnel                           | Environment                                        | Barrier Degradation                                        | Asset Damage /Downtime | Reputation                       | A<br>Never heard of in industry | B<br>Heard of in industry | C<br>Has occurred in Company | D<br>Several occurrences per year in Company | E<br>Several occurrences per year on location or rig |
| 1 | Minor injury<br>FAC                 | Very limited impact<br>< 10 m3                     | No impact on function or reliability/availability          | < 100K USD             | Negligible impact                | Low                             | Low                       | Low                          | Medium                                       | Medium                                               |
| 2 | Moderate injury<br>MTO or RWC       | Minor short term impact<br>10 - 100 m3             | Minor impact on function or reliability/availability       | 100K – 500K USD        | Short term local impact          | Low                             | Low                       | Medium                       | Medium                                       | High                                                 |
| 3 | Serious injury<br>LTI               | Moderate short/medium term impact<br>100 - 1000 m3 | Moderate impact on function or reliability/availability    | 500K – 5M USD          | Medium to long term local impact | Medium                          | Medium                    | High                         | High                                         | Serious                                              |
| 4 | Single fatality or severe injury    | Long term localised impact<br>1000 – 10,000m3      | Significant impact on function or reliability/availability | 5M – 25M USD           | National concern                 | Medium                          | High                      | High                         | Serious                                      | Serious                                              |
| 5 | Multiple fatalities/severe injuries | Widespread long term impact<br>> 10,000 m3         | Barrier function lost                                      | > 25M USD              | International concern            | High                            | Serious                   | Serious                      | Serious                                      | Serious                                              |

**Figure 9-5: SDL Risk Classification Matrix**

### 9.3.5 Safety and Environmentally Critical Elements (SECE) identification

A fundamental aspect of risk identification and evaluation is the identification of critical barriers: the failure of which could cause or contribute substantially to a major accident, or whose purpose is to prevent or limit the effect of a major accident. These barriers are referred to as safety and environmental critical elements (SECEs). The SECEs associated with the MODU are provided by Stena Drilling and listed below,

**Table 9-4: Safety and Environmentally Critical Elements (SECE)**

| ID | SECE                       | ID | SECE                               |
|----|----------------------------|----|------------------------------------|

### 9.3.5.1 SECE Performance Standards

Based on the list of SECEs detailed in Table 9-4 above, suitable functional requirements have been developed to assist in effective management and maintenance of the systems. These requirements are called Performance Standards (PS).

The minimum standards that SECEs are required to maintain to achieve the specified safety goal are defined in the PS. The standards define the SECE functionality, as well as qualitative and quantitative performance criteria for each SECE. A Verification Scheme has been developed by SDL to ensure independent verification that the SECEs meet their performance standards throughout their life cycle.

Performance standards are established for SECEs in terms of:

- **Functionality:** A statement of the performance required of the SECE to fulfil its role
- **Availability:** A statement of the required availability of the SECE
- **Reliability:** For some active systems, the minimum required reliability is stipulated
- **Survivability:** The required performance of the system following an emergency
- **Interactions:** The identification of the dependency of the SECE on the operation of other SECEs

### 9.3.5.2 SECE Assurance

A risk-based, results-oriented maintenance system for the DrillMAX is in place, reflecting good industry practice and focusing on ensuring the performance of SECEs. A holistic management approach is taken to ensure that internal QA/QC, planned maintenance, and the holding of essential spares onboard for the SECEs are targeted at reducing the risks to personnel and the environment to a level as low as reasonably practicable.

The primary goals of the maintenance system are,

- The DrillMAX shall be operated and maintained in a manner that reduces all risk related to HSE to a level as low as reasonably practicable.
- The maintenance activities shall contribute to an early identification of critical failures and optimised availability of critical vessel systems and equipment.

The DrillMAX maintenance system is based on the maintenance management loop illustrated in Figure 9-6, which identifies the key elements of a risk-based continuous improvement system.

Figure 9-6: Stena DrillMAX Maintenance Management Loop

## 9.4 Hazards identification

### 9.4.1 Hazards identification

The hazards identified and assessed from the existing DrillMAX QRA, based on the Asopus-1 project activities, are listed below,

- Blowouts (during drilling)
- Fires, Explosions and Toxic Releases
- Marine Events
- Other Hazards

The following scenarios have been identified and assessed from report as below,

#### Blowouts

- Well releases located on the drill floor
- Blowouts located on the drill floor
- Blowouts located in the moonpool
- Blowouts located in the mud processing room
- Blowouts located subsea

#### Fires, Explosions and Toxic Releases

- Fire in mud treatment areas
- Release of toxic gas( $H_2S$ )
- Fire in accommodation
- Machinery space fires

#### Marine Events

- Ship collision
- Passing vessel collision
- Attendant vessel collision
- Structural failure
- Reduction in stability
- Loss of dynamic positioning system

#### Other Hazards

- Dropped Objects
- Occupational risks
- Transport – Helicopter accidents
- Helicopter crash on the MODU

### 9.4.2 Identification of major accident scenarios

The MAH's identified from the existing Hazard Register and used in the QRA assessment are listed in **Table 9-5**.

**Table 9-5: Assessed Major Accident Hazards**

| ACCIDENTAL EVENT                                       |                                                                             | RISK TO PERSONNEL | RISK TO ENVIRONMENT | MAH | MEI | NON-MAH |
|--------------------------------------------------------|-----------------------------------------------------------------------------|-------------------|---------------------|-----|-----|---------|
| <b>1. Blowout and Well Releases</b>                    |                                                                             |                   |                     |     |     |         |
| 1.1                                                    | Well release                                                                | H                 | M                   | X   |     |         |

### 9.4.3 Hydrocarbon release scenarios

#### 9.4.3.1 Blowouts and well releases

A blowout is defined as an uncontrolled release of fluid from a well. The most significant hazard associated with these releases is the uncontrolled release of hydrocarbons to the surface. Drilling mud, completion fluid, or water may also be blown out in the process.

Analysis of blowout risks is important because they have the potential to release large amounts of hydrocarbons, are difficult to control, could inflict significant damage to the drillship and the environment, and pose a major threat to personnel.

The blowouts risk evaluation consists of the following:

- Hazard identification
- Blowout frequency estimation
- Consequence evaluation
- Risk summation
- Risk reduction measures

#### Hazard Identification

Well control systems are designed to prevent uncontrolled flow of releases of formation fluids from the well. Normally, three levels of well control procedures are distinguished as follows:

1. Primary well control systems are designed to prevent uncontrolled flow of formation fluids from the formation by maintaining hydrostatic pressure with drilling mud and MPD backpressure, if applicable.
2. Secondary well control systems are established to control the well in the event of an unscheduled flow and primary control failure. Control of the well at this level normally requires the use of the blowout preventer (BOP).
3. Tertiary well control systems can be implemented to prevent loss of control when secondary procedures fail. This could involve an independent shut-in device or other methods that involve pumping, such as barite, gunk, or cement plugs.

In the unlikely event these three layers fail to regain control of the well, a blowout may result. The scenarios which have been identified during the operation of the MODU are as follows,

- Hydrocarbon blowouts located on the drill floor.
- Hydrocarbon blowouts located in the moonpool.
- Hydrocarbon blowouts located in the mud processing room (shale shakers).
- Hydrocarbon blowouts located subsea.
- Shallow gas blowouts.

In addition to the fire and explosion hazards posed by blowouts, toxic gas (H<sub>2</sub>S) may be present in harmful concentrations within the reservoir or formation being drilled. When released on or near the drillship, toxic gas may constitute a major accident event. Toxic gas released on the MODU would normally be coincident only with a well control problem.

However, H<sub>2</sub>S may also occur in the shaker area where the mud is first exposed to the atmosphere. For the drillship, H<sub>2</sub>S detectors are installed in areas where H<sub>2</sub>S may occur during normal operations. If operations are planned in areas with a known or potential H<sub>2</sub>S hazard, the drilling Contractor SDL shall take special precautions when preparing and carrying out the drilling operations.

Shallow gas releases are assumed to occur subsea, consistent with the existing QRA. At the Asopus-1 water depth of approximately 840 m, a substantial proportion of released gas is expected to dissolve in the water column, while any gas reaching the surface is expected to disperse over a broad area. On this basis, shallow gas releases are assessed as presenting a low risk to personnel and the MODU at the sea surface.

#### 9.4.3.2 Fires, explosions and toxic releases

##### Fire in mud treatment areas

The mud system on the MODU treats, stores, and circulates the drilling fluid required for all planned and emergency operations.

The three main mud treatment areas are as follows:

- Mud pits.

- Shale shaker room (mud process area).
- Mud pump room.

The mud pits and shale shaker room are mechanically ventilated with under-pressure in relation to non-hazardous and Zone 2 areas.

The possible causes of explosions in the mud treatment areas include gas buildup from

- High concentration or large quantity of gas returned while circulating out a kick.
- Inadequate ventilation system, resulting in it being impossible to prevent gas buildup from the gas-cut mud.

### **Release of Toxic Gas (H<sub>2</sub>S)**

The storage and use of hazardous or potentially toxic materials kept onboard is strictly controlled by MODU procedures. This risk assessment has not considered the risks due to the release of such materials.

Toxic gas (H<sub>2</sub>S) may exist naturally in the reservoir. Significant quantities of H<sub>2</sub>S could be released in an unlikely scenario of a well control event, including while circulating out a kick or during a blowout. No well testing is planned as part of the Asopus-1 campaign.

H<sub>2</sub>S may also become entrained in the drilling mud and be brought onboard with the mud returns. Small toxic gas releases resulting from normal or primary well control operations or from core breakout are controlled by standard contingency procedures.

### **Other Fires**

Other fire events include all fires and explosions not related to well operations. Such fires/explosions may involve hydrocarbons (typically helifuel, diesel, lube oil, etc.) or be non-hydrocarbon fires (e.g., accommodation, electrical, or chemical fires).

Although most of these fires are limited both in size and duration (e.g. a chip-pan fire in the galley lasting a few seconds), some recorded events have been larger causing severe damage and fatalities. The frequency of these fires may be higher than that of fires related to well operations, suggesting they should not be overlooked when establishing the overall risk picture, even though the consequences are likely to be smaller.

The other identified hazards are as follows:

- Fire in accommodation
- Fire in main engine rooms

### **Fire in Accommodation (Living Quarter / Temporary Refuge)**

The accommodation on the drillship has capacity for 180 persons. Based on historical evidence, the following areas are the most likely sources of accommodation fires.

Galley Fire - Cooking presents a potential fire hazard. A galley fire could destroy the galley and possibly smoke-log the accommodation; however, fire spread is unlikely, and it is considered that there is minimal potential for galley fires to develop into major accidents.

Laundry Fire - Drying overalls with residual oil traces present a fire risk, as does the accumulation of lint in the dryer exhausts. A laundry fire is unlikely to spread beyond the compartment since the combustible

inventory is limited and the construction is fire-rated; however, the accommodation could become smoke-logged.

On the drillship, the main control room is located above the accommodation block. In the event of an escalated accommodation fire, the integrity of the control room could be compromised, leading to control room impairment.

### Fire in Main Engine Room

There are three main engine rooms located at the aft of the vessel. Each room contains 2 diesel generators. The exhaust ducts from the engines are routed up and above the upper deck level. The engine rooms are protected by gas, smoke and flame detection, a fire alarm push-button, a fixed CO<sub>2</sub> extinguishing system, portable firefighting equipment, and fire hose stations.

A fire in one of the main engine rooms could involve a potentially large volume of fuel oil. Engine room fires may begin with a fractured fuel line or a fuel leak that comes into contact with a hot surface, such as an exhaust manifold. Oily rags left close to or in contact with hot machinery surfaces and welding work can also initiate small fires in machinery spaces. Fuel-oil cut-off valves are provided and can be remotely operated from outside the main engine rooms.

## 9.4.4 Non-Hydrocarbon release scenarios

### 9.4.4.1 Marine events

#### 9.4.4.1.1 Ships collision

During normal offshore operations, the MODU will be exposed to collision risks from marine vessels. These vessels include passing merchant vessels, fishing vessels in transit and supply vessels destined for the drillship location.

The risk from drifting vessels is considered low as the time between detection and a potential collision with the drillship should be more than adequate to allow for an organised relocation or evacuation of the drillship.

The results presented are based on the implementation of operational procedures to detect errant vessels and initiate measures to prevent collisions.

The MODU is assumed to operate with a nearby support vessel and an Automatic Radar Plotting Aid (ARPA), and the drillship is required to disconnect and move off if required. It is taken into consideration that procedures will focus on ensuring that the disconnection of the riser is initiated early enough to allow the drillship to move out of the errant vessel's path.

For the MODU, there are two primary ways of avoiding collision once a threat has been confirmed through the use of the ARPA (or via visual observation).

- Warning the vessel causing a threat, using available means of communication.
- Disconnecting and moving the drillship to a safe location.

For the drillship's ARPA to be effective in preventing collisions, the drillship's onboard communication systems must be used to contact ships that pose a risk to the drillship. Action must then be taken on the approaching vessel in order to avoid collision. The nearby support vessel can also be used to avert a collision by turning towards the approaching vessel and using sound and light signals. However, for the approaching vessel to respond to radio calls, sound, or light signals, the bridge must be manned, and the vessel's personnel must be able to carry out appropriate corrective actions. In the event efforts to establish radio contact with the approaching vessel fail, collisions can be avoided by moving the drillship.

#### 9.4.4.1.2 Structural failure

Factors which may influence or accelerate the structural failure of the drillship include,

- Weakness in structure (e.g. design defect, inadequate design, material or fabrication defect, failure due to incorrect modification, or inadequate maintenance, inspection, and testing).
- Overloading of the structure due to human error or extreme weather.
- Consequences of fires, explosions, reduction of stability, impact (ship collision, helicopter crash, grounding).

Structural failure due to fatigue, corrosion, or extreme environmental loading (Earthquakes, Extreme weather, etc.) may lead to a major accident, either through compartment flooding that reduces stability or through loss of structural strength that causes progressive collapse.

Earthquakes are not considered to have a significant direct influence on the MODU. However, the wellhead / BOP may be exposed to excessive loads. If the drillship is to be operated in areas where there is a significant risk of an earthquake, precautions should be considered for the specialised design of the casing, wellhead, BOP, and connectors, as well as operational procedures.

Some analyses have drawn a distinction between failures in environmental conditions beyond those the installation was designed to withstand (extreme weather) and other failures under less severe conditions that reveal design or construction errors (failures within design). This distinction is not always clear, so the two types of failures are treated together in this report.

#### 9.4.4.1.3 Reduction in stability

A reduction in stability may be caused by flooding following a vessel collision, by structural failure, or by extreme environmental conditions, which are initiated by many of the events that cause critical structural failure identified above. A reduction in stability may lead to vessel capsize, with potential material and environmental consequences.

NORSOK N-003. states that *“for floating structures it should be considered whether a subsea gas blowout can cause loss of buoyancy or a displacement of significance to the stability.”* For a DP/unmoored vessel in water depths of at least 250m (minimum operating water depth for the drillship), the probability of loss of buoyancy or a displacement of significance to the stability is considered to be low as the dynamic forces of a rising gas plume would tend to push the vessel away from the centre of the plume and away from the least buoyant areas. Hence, this scenario is not considered an accidental dimensioning event.

In other events where the vessel suffers a loss of stability, the event may escalate more slowly, allowing personnel time to muster and evacuate the vessel by TEMPSC.

During analysis of the vessel design, the recessed setback area next to the drill floor was identified as potentially prone to flooding under extreme environmental conditions, which could reduce stability.

#### 9.4.4.1.4 Loss of position

Loss of position occurs when the drillship unintentionally moves off. This may be due to a thruster failure, a loss of power, a computer software malfunction, or a reference system failure.

While it is expected that, during drilling operation, provisions would be made for possible deviations from the specified location beyond the operationally tolerable limit, excursions beyond these limits, known as force-off, drift-off or drive-off, could still occur. When operating in DP mode, loss of position is described as drift-off, drive-off, large excursion, or force-off.

The DP control system of the drillship is designed to comply with DNV Class Notation DNV DYNPOS AUTRO (IMO DP Class 3). Thus, meeting the requirement that propulsion and control systems shall be fully redundant so that no single failure can put out both systems

The main contributors to risk from loss of station keeping ability have been identified as:

- Large excursions
- Drift-off
- Drive-off

Each of the above events is discussed in more detail below.

##### Large Excursions

Large excursions imply that the drillship deviates from the specified location by more than what is operationally tolerable. Large excursions are not considered a loss-of-position hazard, as any consequences are purely operational in nature.

##### Drift-off

Drift-off is caused by loss of power from the thrusters, and the behaviour of the drillship will depend upon wind conditions, sea state and current. As a standard, the Stena DrillMAX is expected to operate within the designed environmental limits. Where adverse weather conditions are not foreseen, appropriate measures should be in place to prevent or mitigate any major accident event.

##### Drive-off

A drive-off situation is taken to be a loss of position event due to either:

- A fault in the thrusters and/or their control system.
- A fault in the position reference system

The hazards associated with thruster control could be as follows,

- The MODU drillship has deviated from the reference point, and power in the direction of the reference point is given to the thrusters. The MODU drillship moves towards the reference point.

- The DP control system initiates a command to change the power to the thrusters to stop the drillship at the reference point. The system suffers an on-demand failure and does not respond.
- The drillship overshoots the reference point, and the DP control may increase the power to bring the drillship back to the reference point. The drillship, however, accelerates away from the reference point.
- If the operator does not intervene, the drillship will suffer a critical loss of position.

A drive-off could occur if the DP system, for some reason, obtains an incorrect position reference. The drillship may then move towards the new, wrong reference point.

In the list of potential causes for drive-off, operator error is not included. This is because the drillship is assumed to use automatic mode only either during normal operation or in situations which are difficult to control. Manual mode can be achieved by pressing several buttons to disable automatic mode (i.e., manual mode is not obtained by moving the joystick alone). Using manual mode will introduce more complex error mechanisms, increasing the probability of position loss.

#### 9.4.4.2 Other hazards

##### 9.4.4.2.1 Topsides Dropped objects

Accidentally dropped loads from cranes, drill tower or other lifting devices could result in injuries or fatalities to personnel, release of hazardous material (if the object falls on deck or in the seabed) or damage to the structural support. This risk contribution is usually included in the occupational risk figure. The occupational risk contribution has been removed to avoid double-counting.

The MODU drillship is equipped with three 85 te deck cranes (1 port and 2 starboard). In addition, there is a 7 te pipe-handling knuckle boom crane forward, and dedicated pipe-handling equipment both forward and aft of the drill tower.

The main risk contribution from dropped objects on an offshore installation is typically considered to be the risk of dropped objects striking personnel directly or impacting hydrocarbon-containing equipment (thus initiating leaks, fires, or explosions). Dropped objects may also impact or puncture critical equipment or structural elements. However, there are limited topsides inventories on the MODU drillship; the probability of these events resulting in the impairment of safety function or the need for evacuation is considered to be low. The most likely scenario is damage to the asset, which in most cases may not be significant.

The critical areas identified in the MODU drillship are as follows,

- Accommodation, wheelhouse, control room, and backup DP room.
- Switch / transformer room above the mud pits / mud pumps.
- Setback area.
- Cargo oil storage tanks (protection provided by plated deck above).
- Well test area when in use.
- Engine rooms and engine control room.
- Helifuel storage tanks.

It is assumed that dropped object protection / crane coverage area for the wheelhouse, control room and the backup DP room is in place, and that the helifuel storage tanks will be suitably protected. Further, it is assumed that Stena lifting procedures are in accordance with industry good practice and that there is no lifting over live hydrocarbon-containing equipment.

Hence, the risk contribution from impacts with hydrocarbon-containing equipment resulting in leaks or fires can be considered negligible, and the greatest risk to personnel is being hit, struck, or crushed by a falling or swinging object. Risks due to dropped objects are therefore restricted to direct impact with personnel i.e. falling or striking.

#### 9.4.4.2.2 Subsea Dropped objects

Most MAHs related to dropped objects refer to drillship-dropped objects impacting subsea infrastructure. The exact nature of the subsea infrastructure will change on a well-by-well basis, and meaningful quantification of the annualised risk is not feasible.

As the MODU will be operating in deep water where there is no nearby seabed infrastructure, the likelihood of a dropped object impacting a piece of equipment directly below the vessel is negligible. Any hydrocarbon release following impact on subsea infrastructure will disperse in the water column. Ignition is deemed unlikely as the gas concentration on the deck of the vessel will be below the flammability threshold. The gas column in the water will not displace sufficient water to cause stability issues with the vessel.

#### 9.4.4.2.3 Helicopter Transport (travel accidents)

The helicopter risk to the different personnel groups on the drillship can be assessed using a risk model, taking into account the number of flight stages and takeoffs and landings. Combining this with historical data on accident frequencies at each stage, the risk of helicopter travel is calculated.

The risks have been split into those during the in-flight stage (in the air) and during take-off/landing, with a crash on the installation.

Due to the transient nature of the vessel location, the flight time will change depending on the distance to the onshore heliport. Based on project information, the base-case helicopter flight time is assumed to be 1 hour (30 min each way). Fixed-wing transportation is excluded from this assessment.

##### Helicopter Crash on the Drillship

The risks to personnel on the helicopter resulting from helicopter crashes on the drillship are included in the helicopter transport risk above. However, helicopter accidents on offshore helidecks may affect personnel not inside the helicopter.

Possible scenarios with respect to helicopter crashes are:

- Heavy landing or crash onto the helideck, with potential for a subsequent fire;
- Crash into the control room or bridge due to overshooting the helideck, with potential for impairment of the upper TR due to the resulting fire;
- Crash into the sea; or

- Crash into other areas of the drillship

#### 9.4.4.2.4 Occupational hazards

Occupational accidents are defined as accidents with no potential to cause fatalities outside the immediate area of the incident. Most cases will cause no more than a single fatality.

Occupational accidents include a wide variety of events, such as:

- Falls (to the same level, to a lower level, to the sea).
- Mechanical impacts.
- Burns (e.g. from hot surfaces, open flames from hot work).
- Poisoning, suffocation, asphyxiation.
- Damage caused by tools and machinery.

## 9.5 Frequency Assessment –based on QRA

### 9.5.1 Hydrocarbon release frequencies

#### 9.5.1.1 Topsides blowouts

The base case assumption and sensitivity cases used in the DrillMAX QRA are as follows,

- Base case: 4 HP/HT exploration wells (per year) in the Gulf of America
- Sensitivity case 1: 3 HP/HT development wells and 3 completion operations per year in the Gulf of America
- Sensitivity case 2: 4 HP/HT exploration wells (per year) in the Northwest Atlantic (off the coast of Newfoundland, Canada), and
- Sensitivity case 3: 3 HP/HT development wells and 3 completion operations per year in the Northwest Atlantic (off the coast of Newfoundland, Canada).

For Asopus-1, the plan is to drill only one (1) exploration well. with no well completions and/ or production of hydrocarbons. This assessment uses analysis from only the base case.

The SINTEF offshore blowout database is the primary source of the data used to establish the blowout frequencies for the MODU Stena DrillMAX. The database, updated annually in the SINTEF blowout frequencies report and analysed by Vysus, is considered the most comprehensive and applicable for global operational risk analyses.

The blowout frequencies for the different operational phases of drilling are given in the SINTEF and Vysus reports and are based on operational experience in the US Gulf of America (GOA), the UK, and Norway. A key improvement in this risk assessment is the use of the latest SINTEF and Vysus reports, which contain the most up-to-date frequency data. The data covers the period 1 Jan 1980 to 31 Dec 2022. Blowout statistics from other regions of the world have been excluded from the frequency estimate due to low data quality and

operational standards and practices considered inferior to those in the US Gulf of America (GOA), the UK, and Norway.

To reflect possible changes in frequencies over time, Vysus applies an approach in which new data is given greater weight than old data. This approach consists of a linear weighting of incidents and exposure times from 1980 to 2013. In this manner, data from the last 10 years are treated equally, whereas older data are gradually weighted towards lower significance. Technological and safety standards have considerably improved over time, and the implementation of new safety regulations has changed how drilling operations are planned and carried out.

The frequencies and consequence modelling from the existing Stena DrillMAX QRA base case have been retained for this assessment as a conservative basis. The DrillMAX base case assumes an HPHT exploration well, whereas Asopus-1 is currently expected to encounter normal reservoir pressures and temperatures, with formation pressure limited to hydrocarbon buoyancy. Accordingly, the use of the DrillMAX base case is considered conservative for the purposes of this assessment.

The blowout frequencies and consequence assumptions from the existing Stena DrillMAX QRA have been retained as the conservative basis for the personnel-risk calculations. No quantitative credit has been taken in the reported IRPA, FAR, PLL or Main Safety Function impairment results for the lower expected Asopus-1 reservoir conditions or for the additional risk reduction provided by the project-specific E-SID.

The blowout frequency for the exploration drilling well, based on analysis of the SINTEF database as published in the SINTEF and Vysus report, is used in Table 9-6 below,

**Table 9-6: Blowout Frequency for Exploration Drilling Well Operation**

| OPERATIONAL PHASE             | WELL RELEASE | BLOWOUT  | UNIT     |
|-------------------------------|--------------|----------|----------|
| Exploration Drilling (Normal) | 9.23E-04     | 1.20E-04 | Per well |
| Exploration Drilling          | 5.72E-03     | 7.42E-03 | Per well |

The blowout flow-paths and release points for the deep blowout exploration well based on the SINTEF Offshore Blowout Database are in Table 9-7 below,

**Table 9-7: Release Location Vs Exploration Well (Operating Phase)**

| BLOWOUT TYPE             | DRILL FLOOR | MOONPOOL | SHAKER HOUSE | SUBSEA |
|--------------------------|-------------|----------|--------------|--------|
| Deep Blowout Exploration | 0.25        | 0.03     | 0.03         | 0.69   |

The flow rates for the different blowout scenarios will vary depending on the type of well drilled. The flow rates used in this assessment, based on the existing QRA, are as detailed in Table 9-8.

**Table 9-8: Blowout Rates**

| WELL TYPE    | FULL FLOW  | CHOKE / RESTRICTED FLOW |
|--------------|------------|-------------------------|
| Normal wells | 130 kg/sec | 26 kg/sec               |
| HPHT wells   | 260 kg/sec | 52 kg/sec               |

As with the existing QRA, the ignition probability for oil and gas blowouts has not been differentiated. This is because the flashing of the well stream from an oil reservoir normally results in a significant gas release in addition to the oil. A generic ignition probability has been used in this analysis; it pertains to early ignition (i.e., within 5 minutes) of the releases. The ignition probability is presented in Table 9-9:

**Table 9-9: Ignition Probabilities for Blowouts**

| INCIDENT             | IGNITION PROBABILITY |
|----------------------|----------------------|
| Topside Deep Blowout | 0.13                 |

Table 9-10 presents the blowout frequencies applied in the Asopus-1 personnel-risk calculations. These frequencies are retained from the existing Stena DrillMAX QRA basis rather than recalculated using the project-specific E-SID reliability result.

**Table 9-10: Blowout Frequencies Per Year**

| BLOWOUT TYPE   | BASE CASE (HP/HT EXPLORATION WELL) |
|----------------|------------------------------------|
| Drillfloor     | 7.42E-04                           |
| Moonpool       | 9.28E-05                           |
| Shale Shaker   | 9.28E-05                           |
| Subsea         | 2.04E-03                           |
| Total Blowouts | 2.97E-03                           |

Based on the analysis of the SINTEF Offshore Blowout Database, the average immediate fatalities for HPHT wells from the existing DrillMAX QRA are shown in Table 9-11 below. These values have been retained as a conservative basis for the Asopus-1 assessment.

**Table 9-11: Average Immediate Fatalities**

| AREA                            | AVERAGE IMMEDIATE FATALITIES |      |
|---------------------------------|------------------------------|------|
|                                 | NORMAL                       | HPHT |
| Ignited blowout on              | 1.5                          | 4    |
| Ignited blowout in shaker house | 2                            | 2    |
| Unignited                       | 0.12                         | 0.12 |

Ignited well releases are assumed to result in one immediate fatality. Well releases are controlled by barriers in place at the time of the release, e.g. BOP. Hence, well releases are not considered to escalate or necessitate drillship evacuation.

The following rule applied in the existing QRA has been replicated here to calculate evacuation and escape fatalities for the specific blowout scenarios considered:

- If the MODU cannot move off location, personnel will attempt to abandon the vessel using the TEMPSC irrespective of whether the blowout has ignited.
- If the TEMPSCs do not function either due to mechanical failure or because they are impaired, personnel unable to evacuate would escape to sea using escape chutes and liferafts.

Two categories of fatalities have been defined as follows,

- Immediate fatalities - restricted to members of the operational worker group, i.e. drilling personnel.

Immediate fatalities are considered to occur even with a warning of a blowout, as it is assumed that the drill crew would still be attempting to control the kick when the blowout occurs.

- Evacuation / support vessel fatalities – fatalities because of drillship evacuation and/or escape to sea.

### 9.5.1.2 Project-specific well control barrier. K-BOS E-SID

In addition to the well-control barriers considered within the existing Stena DrillMAX QRA, the Asopus-1 campaign will deploy the K-BOS Emergency Shut-In Device (E-SID) supplied by Kinetic Pressure Control. The E-SID is an independently actuated subsea shear-and-seal device installed below the Stena DrillMAX subsea BOP stack, providing an additional well-control barrier independent of the primary BOP control system.

The E-SID forms a third layer within the project-specific well-control barrier hierarchy, supplementing the primary well barrier and the Stena DrillMAX BOP system. In the unlikely event that conventional well-control measures and BOP intervention fail to achieve or maintain well isolation, the E-SID provides an additional means of isolating the well at the wellhead through an independent shear-and-seal mechanism. The device is pre-installed as part of the drilling system and is available throughout drilling operations.

The existing Stena DrillMAX QRA provides the conservative basis for the quantified MODU personnel-risk results, without quantitative credit for the additional E-SID risk reduction. The project-specific E-SID reliability assessment is used separately to determine the representative environmental loss-of-containment scenario for the ESIA and to support the well-control ALARP demonstration.

Independent probabilistic reliability assessments undertaken for the combined BOP and E-SID configuration indicate a substantial reduction in blowout probability compared with a conventional BOP-only configuration. The Project-specific analysis indicates that the estimated probability of an uncontrolled blowout decreases from  $1.20 \times 10^{-4}$  to approximately  $2.08 \times 10^{-8}$  per well after deployment of the E-SID.

On this basis, a sustained uncontrolled subsea blowout is not adopted as the representative environmental loss-of-containment scenario for the Asopus-1 ESIA. The K-BOS E-SID provides material project-specific risk reduction and supports the demonstration that well-control risks have been reduced to ALARP.

The representative environmental release scenario adopted for the ESIA is an instantaneous loss of 350 m<sup>3</sup> of Marine Gas Oil from a fuel tank on board a Platform Supply Vessel supporting the drilling campaign. The transport, weathering and fate of this release are assessed through the oil spill modelling (Section 9.7).

This conclusion does not remove the requirement to maintain contingency source-control and emergency-response arrangements for more severe escalation scenarios, including BOP intervention, capping, containment and relief-well planning.

### 9.5.1.3 Fires in mud treatment areas

The data and assumptions used in the analysis of the fires in the mud treatment are as follows,

- The frequency of fires in the mud system is 8.14E-03 per year, based on 9 mud area fires in 1105 years of MODU operations in the UKCS.
- Of all the reported mud area incidents examined, none was found to escalate beyond the area of initiation. However, the QRA assumed that 1.5% (i.e. probability of 0.015) of all incidents will escalate to

surrounding areas. The escalation probability assumes that the mud processing areas will be equipped with appropriate protection measures to minimise the likelihood of escalation

- Escalation to the LQ/ TR is considered remote.
- Environmental damage is considered to be negligible for all scenarios.
- All ignited events have 1 immediate fatality.
- People away from the immediate vicinity are assumed to be unharmed.
- Evacuation is not considered necessary since the LQ is unlikely to be impaired.

#### 9.5.1.4 Release of toxic gas

---

The data and assumptions used in the analysis of the release of toxic gas are as follows,

- Consistent with the existing DrillMAX QRA, sour gas blowouts are assumed to result in 3 immediate fatalities.

#### 9.5.1.5 Other fire events

---

##### 9.5.1.5.1 Fire in Accommodation (Living Quarter / Temporary Refuge)

The frequency of fires in the accommodation is estimated to be 1.42E-02 per year based on inspection of UK HSE accident databases (21 accommodation incidents in 1416.3 floating unit years of operation in UKCS). Most of the accommodation fires reviewed were minor, causing little or no damage. However, the QRA assumed an escalation probability of 1%, and in the event of escalation, a single fatality is assumed, based on the provision of detection in all spaces and an accommodation water sprinkler system.

##### 9.5.1.5.2 Fire in main engine rooms

The data and assumptions used in the analysis of fires in main engine rooms are as follows,

- Escalation is considered unlikely in view of the safeguards in place, however, a probability of 1% has been assumed.
- In events where firefighting is ineffective one immediate fatality is assumed.
- Potential environmental damage is considered to be negligible.
- The frequency of fires has been increased by a factor of 2 to reflect the fact that there are 3 engine rooms.
- Engine room fires are not considered to result in TR impairment.

## 9.5.2 Non-Hydrocarbon release frequencies

### 9.5.2.1 Ship collision

The frequency of a ship colliding with the drillship is a function of the level of the vessel traffic in the area and the preventative measures available to avert a collision, and therefore a location-specific risk assessment should be undertaken any time the drillship is operating in a new location.

From the QRA and for the purposes of this analysis, the average passing collision frequency has been estimated from the HSE database. An examination of the database shows a total of 1 passing-vessel collision between MODUs and vessels in 1100.1 MODU years. This gives a total collision frequency of 2.1E-03 per year and a frequency of collisions resulting in damage of 9.09 E-04 per year. As the MODU can disconnect from the well and move off location on DP, this value is taken as the frequency of a vessel being on a collision course.

For the MODU drillship, there are two primary ways of avoiding collision once a threat has been confirmed through the use of the ARPA (or via visual observation).

- Warning the vessel causing a threat, using available means of communication.
- Disconnecting and moving the drillship to a safe location.

For the drillship's ARPA to be effective in preventing collisions, the drillship's onboard communication systems must be used to contact ships that pose a risk to the drillship. Action must then be taken on the approaching vessel to avoid collision. The nearby support vessel can also be used to avert a collision by turning towards the approaching vessel and using sound and light signals. However, for the approaching vessel to respond to radio calls, sound, or light signals, the bridge must be manned, and personnel on board the vessel must be able to carry out appropriate corrective actions. In the event efforts to establish radio contact with the approaching vessel fail, collisions can be avoided by moving the drillship. Several causes that may result in the approaching vessel not responding to the signals from the drillship (or the attendant vessel) are listed in Table 9-12 below.

**Table 9-12: Probability Of Unsuccessful Correction of Vessel on Collision Course**

| ERROR MODE                   | FRACTION OF ERRANT VESSEL WHERE ERROR MODE IS PRIMARY CAUSE OF VESSEL BEING ON COLLISION COURSE | PROBABILITY OF RADAR / RADIO BEING INADEQUATE MEASURE TO PREVENT COLLISION |
|------------------------------|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Crew absent from bridge      | 24%                                                                                             | 0.9                                                                        |
| Crew absorbed in other tasks | 20%                                                                                             | 0.5                                                                        |
| Accident on vessel           | 4%                                                                                              | 0.9                                                                        |
| Crew asleep                  | 8%                                                                                              | 0.6                                                                        |
| Crew intoxicated             | 4%                                                                                              | 0.8                                                                        |
| Radar failure                | 40%                                                                                             | 0.5                                                                        |
| <b>Total</b>                 | <b>100%</b>                                                                                     | <b>0.63</b>                                                                |

The probability of the ARPA being used and being unsuccessful in preventing the collision is therefore taken to be 0.63 (given ship on collision course). A review of available AIS and marine traffic information for the Asopus-1 location confirmed that the adopted collision frequencies remain conservative.

Moving the drillship off location is assumed to be successful 95% of the time this operation is deemed necessary. The operations involved in disconnecting are assumed to be technically successful almost every time they are initiated. For instance, the decision to carry out an emergency disconnection must be made early enough to allow the drillship to move the required distance to prevent a collision. The assigned successful move off probability of 95% is therefore considered to be conservative. The annual collision frequencies are shown in Table 9-13, depending on whether the ARPA system is actively used and move-off is initiated.

**Table 9-13: Annual Collision Frequency**

| MEASURES                                                                                                        | FREQUENCY PER YEAR |
|-----------------------------------------------------------------------------------------------------------------|--------------------|
| Frequencies if only a nearby support vessel is available                                                        | 9.09E-04           |
| Frequencies if ARPA radar and radio are actively used                                                           | 3.36E-03           |
| Frequencies if ARPA radar and radio are used, and the drillship takes measures to move off location if required | 1.68E-05           |

In the case of the drillship, the risks are assessed assuming ARPA and radio are used and that the drillship takes measures to move off location if required, i.e. a frequency of 1.68E-05 per year is used.

### 9.5.2.2 Structural failure

Historically, structural failures have been caused by the development of large cracks in the hull resulting from brittle fracture, corrosion, excessive local stresses causing ingress of water into cargo tanks, ballast tanks or engine rooms, and ultimately resulting in the vessel sinking. It is assumed that rigorous procedures will be in place to detect and repair cracks in the hull at an early stage, thereby significantly reducing the risk of unexpected catastrophic structural failure.

The annual frequency of structural failure is taken to be 3.2E-04, and this is the frequency of severe structural failure for all non-fixed units (excluding failures during towing) from IOGP 434.

### 9.5.2.3 Reduction in stability

The frequency of capsizing a vessel largely depends upon the environmental conditions experienced. A generic frequency of capsize of 5.7E-05 per year in severe weather is assumed to be based on the CMPT Guide to QRA for Offshore Installations. In moderate-to-calm conditions, this frequency is 1.69E-06 per year.

### 9.5.2.4 Loss of position

Based on historical data published by the International Maritime Contractors (IMCA) from loss of position incidents reported up to 2022 for all types of DP vessels which reports a total of 205 incidents by 600 vessels between 2015 and 2022 with a combined operating time of 2.35 million hours.

These incidents are inclusive of DP2 and DP3 vessels and as the MODU is a DP3 vessel, a 20% reduction has been applied to the loss of position statistics giving a frequency of 0.27 operating year (based on a 45% fraction of the year operating on DP). The IMCA collects statistical data from DP operated vessels around the world (data between 2015 and 2022 has been used in this assessment). Probability values of 25%, 46% and 28% have been assigned to drive-off, drift-off and large excursion.

### 9.5.2.5 Dropped objects

The frequency of dropped objects is taken from a study of incidents on MODUs in the UK during the period 1980 to 1998 based on incidents reported to the HSE during this time and scaled for the predicted number of lifts in the appropriate load category. Table 9-14 shows the frequency data used.

**Table 9-14: Dropped Object Frequency Data**

| FREQUENCY DATA                                 | ONTO INSTALLATION | INTO SEA | ONTO SUPPLY VESSEL | FATALITIES PER FATAL EVENT |
|------------------------------------------------|-------------------|----------|--------------------|----------------------------|
| Frequency of main crane drop loads per year    | 2.03E-01          | 3.65E-02 | 5.06E-02           | 1                          |
| Frequency of drops from drill tower per year   | 2.90E-01          | 1.82E-02 | 1.66E-03           | 2                          |
| Frequency of drops from other devices per year | 1.63E-01          | 2.32E-02 | 8.29E-04           | 1                          |

The frequencies of a fatality resulting from a dropped object are inherently captured under occupational risk and as a result the dropped object risks calculated are a subset of this. As a result, the overall risk results are not altered by the presence of dropped object risk calculations and instead only the %contribution will change. Given that the data used in the model specific to dropped object risks is old the availability of new technology which removes the manual handling aspect of dropped objects (this is particularly appropriate for the making up of drill string during running in hole and pulling out of hole as a result the likelihood of a drop occurring is reduced and also the likelihood of that drop resulting in a fatality is reduced. This means that the process described here is conservative in spite of the results having no bearing on the final risk results.

### 9.5.2.6 Occupational risks

Accident statistics are reported in the UK by the HSE, in Norway by the Petroleum Safety Authority (PSA) and worldwide by both the International Association of Drilling Contractors (IADC) and International Association of Oil and Gas Producers (IOGP).

Using the approach defined in IOGP 434-12, the following occupational risks have been identified

- Worldwide fatal accident rate – 1.37 per 10<sup>8</sup> exposed hours
- Modification factor for specific function – 1.6 (North Sea – drilling) and 0.1 (admin / catering)
- Location factor – 0.92 (offshore)
- Shift pattern – 12 hours on / 12 hours off – off-shift personnel.

In the absence of a specific location factor for Greece, the factor adopted in the existing DrillMAX QRA has been retained for consistency with the established methodology.

The FAR values for occupational risk per worker group are detailed in Table 9-15.

**Table 9-15: Occupational Hazards Fatal Accident Rates**

| RISK CONTRIBUTOR  | FATAL ACCIDENT RATE (PER 10 <sup>8</sup> EXPOSED HOURS) |             |               |
|-------------------|---------------------------------------------------------|-------------|---------------|
|                   | GROUP 1                                                 | GROUP 2     | GROUP 3       |
|                   | OPERATIONAL                                             | MAINTENANCE | ACCOMMODATION |
| Occupational risk | 2.35                                                    | 2.35        | 0.15          |

## 9.6 Consequence assessment

Consequence assessments have been carried out to determine the impacts beyond the immediate vicinity of the events, based on the scenarios detailed below.

In this analysis, four release locations (drill floor, moonpool, shaker house and subsea) have been considered and the effects of the following:

- Fires (effects from ignited blowouts)
- Smoke dispersion from ignited blowouts
- Gas dispersion from unignited blowout

The explosion analysis was undertaken in the QRA using the DNV COMEX software tool, and each consequence was evaluated at the specified release location using the latest version of the internationally recognised DNV Phast consequence analysis software. The output from this consequence analysis was used in the impact analysis to evaluate the number of fatalities and the likelihood of safety function impairments.

Note 1: The consequences applied in this assessment are derived from the existing Stena DrillMAX QRA. Where applicable, the resulting risk estimates have been adjusted to reflect the single-well Asopus-1 campaign and the project-specific personnel-on-board assumptions.

### 9.6.1 Thermal and radiation effects

A drill floor fire that ignites immediately will burn as jet fire. Delayed ignitions are likely to result in explosions that would cause significant damage to the steel weather protection, generating missiles and other debris. Following an explosion, the blowout will continue to burn.

The drill floor and monkey board level are protected by weather cladding, but the drill tower is otherwise open. Flames could fill the entire drill floor and drill tower area and will be issued from normal openings in the drill tower.

For an ignited drill floor blowout, there is little protection in areas on the open upper deck levels of the vessel. Ignited drill floor blowouts were modelled in the QRA as jet fires with a composition of 80% methane and 20% pentane.

Jet fires were modelled at three wind speeds (1.5m/s, 5m/s and 15m/s). Thermal radiation and smoke from an ignited drill floor blowout could impair the TR and lifeboats or cause the drill tower to collapse if the event escalates.

Delayed ignition may result in a flash fire or explosion, generating significant overpressure that can damage critical equipment or cause fatalities. Unignited blowout events are modelled as gas dispersion using propane as the representative material.

Gas ingress to the TR may cause asphyxiation or explosion if ignited. Radiation contours have been produced to determine the impact of drill floor fire at the living quarter and lifeboat locations; refer to QRA. The impairment probabilities for the forward and at TEMPSC based on the radiation consequence modelling are shown below (Table 9-16, Table 9-17).

**Table 9-16: Forward TEMPSC Impairment Probabilities**

## 9.6.2 Smoke & gas dispersion modelling

The smoke plume from an ignited blowout could overcome escaping personnel or engulf the living quarter and possibly result in fatalities. Smoke and gas following a blowout have been modelled in PHAST. As a conservative estimate the concentration of smoke or gas at the HVAC inlet has been assumed to be the maximum concentration of gas or smoke 67m downwind of the drillfloor and moonpool at an elevation of 40m. The height of the gas or smoke plume relative to the HVAC inlet has been ignored for added conservatism and to try to estimate the effect of the vessel structure. For example, gas and smoke coming from the moonpool will hit the vessel structure, lose momentum, and spread out.

Smoke has been modelled as hot nitrogen with a flowrate 16 times greater than the blowout flowrate. The concentrations estimated at the HVAC inlet are listed below:

- Full blowout from drillfloor
- Smoke - 0.71% (7,050 ppm)
- Gas - 0.42% (4,150 ppm)
- Restricted blowout from drillfloor
- Smoke - 0.22% (2,160 ppm)
- Gas - 0.10% (1,000 ppm)
- Full blowout from moonpool
- Smoke - 2.49% (24,900 ppm)
- Gas - 0.42% (4,150 ppm)
- Restricted blowout from moonpool
- Smoke - 0.33% (3,250 ppm)
- Gas - 0.33% (3,350 ppm)

The impairment criteria give the threshold values of the materials that make up the smoke plume. Like the smoke plume graph, the criteria provide input to enable calculation of the time to impairment. Smoke impairment criteria have been specified as per Table 9-18.

**Table 9-18: Smoke Impairment Criteria**

| MATERIAL        | THRESHOLD | DESCRIPTION                                                                                                                                              |
|-----------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Carbon monoxide | 0.15%     | Limit for impairment of an escape route in 30 minutes. Escape is considered possible in 30 minutes without any escape-impairing or irreversible effects. |
| Carbon dioxide  | 10%       | Limiting concentration for escape actions lasting a few seconds. If escape action is not possible in a few seconds, death is assumed to occur.           |
| Smoke density   | 10 dB/m   | Approximately 1m visibility for un-illuminated objects.                                                                                                  |

| MATERIAL         | THRESHOLD | DESCRIPTION                                                           |
|------------------|-----------|-----------------------------------------------------------------------|
| Temperature      | 40 °C     | -                                                                     |
| Oxygen depletion | 16%       | Limiting oxygen concentration for impairment of an escape route or TR |

### Smoke and Gas Impairment Times

Under normal operating conditions, the impairment potential for the TR due to smoke and gas from blowouts is assessed to be low, as the TR will normally be located upwind of the drilling derrick. However, impairment could occur under abnormal conditions, such as loss of HVAC isolation, failure of automatic shutdown systems, loss of TR integrity, or vessel manoeuvring during an emergency response.

Gas releases from small blowouts are assessed to produce flammable concentration at the nearest TR air intake. Although the gas concentration is estimated at 50% LFL, ignition may still be possible if the gas cloud finds an ignition source. Provided the air intake or other possible ingress routes are not breached the TR is unlikely to be impaired within the 60 minutes endurance time.

Similarly, smoke impairment of the TR may occur if the HVAC fails to shut down or where hermetic sealing is lost. Impairment is estimated to occur within 2 minutes. Where the TR is sealed before a restricted blowout event, the temporary refuge is unlikely to be impaired within the endurance time of 60 minutes.

The integrity of the HVAC is therefore critical to the ability of the TR to provide the necessary safety function.

### Subsea Blowouts

Hydrocarbon fluid from subsea blowouts rise to the surface due to their relatively low density. Gas releases rise rapidly, expanding as the hydrostatic pressure reduces. For oil with a significant gas component, the oil may be entrained in the gas flow and rise almost vertically to the surface with little dispersion in the water column. Methane gas has been used as the worst-case representative gas as it is relative less dense than ethane or propane.

DNV PLUMERISE software has been used to enable the analysis of gas dispersion through water column and the calculation of parameters such as plume diameter, gas velocity and surface concentration which can then be used as input to surface dispersion modelling.

The Asopus-1 water depth of approximately 840 m lies within the range assessed in the existing DrillMAX QRA and therefore the conclusions of the subsea blowout dispersion assessment remain applicable. At these depths, a sustainable flammable gas cloud at the topside is considered unlikely. The maximum concentration for a flammable cloud at water depth of 500 m is estimated at 3% of methane,

Of the 24 subsea blowouts included in the dataset used in the QRA. 2 of the blowouts ignited. In both cases the water depth was less than 100 m. The water depth of this Asopus-1 well is 840m, hence a sustainable flammable gas cloud at the topside due to subsea blowout is not expected.

## 9.6.3 Fire in mud treatment areas

The QRA assumed that 1.5% (i.e. probability of 0.015) of all incidents will escalate to surrounding areas. The escalation probability assumes that the mud treatment areas will be equipped with appropriate protection measures to minimise the likelihood of escalation.

Based on all of the reported mud area incidents examined in the QRA, none was found to escalate beyond the area of initiation. Hence, consequence modelling for the fire in mud treatment area was not carried out and is excluded in this report.

#### 9.6.4 Release of toxic gas

Detection and mitigation measures in place are assumed to include H<sub>2</sub>S detectors located in the areas where gas is most likely to be released. Detection of toxic gas (10 ppm) will give alarm. High toxic gas (20 ppm) will initiate relevant emergency shutdown actions, including automatic control of the ventilation system in the related area.

The drillship crew is likely to be aware in advance of drilling into a potentially sour reservoir and appropriate additional measures to manage the H<sub>2</sub>S hazard would be put in place.

Toxic gas (blowout) events were modelled in the QRA assuming that, in the event of an unignited blowout resulting in the release of toxic gas, the vessel will attempt to move off location. LQ impairment is unlikely, as the LQ will normally be upwind of the drilling area. In this scenario, it was assumed that there is a 93% probability that the HVAC system shuts down successfully and that the TR is not impaired. TR impairment is unlikely, as the TR will normally be upwind of the drilling area.

#### 9.6.5 Other fire events

In the event of an escalated accommodation fire, the integrity of the control room could be compromised, leading to control room impairment and on the MODU, the main control room is located above the accommodation block. Fire in the main engine room is not considered to result in living quarter impairment.

#### 9.6.6 Ship collision

If an errant vessel is heading towards the drillship, it will attempt to communicate with the vessel to determine her status i.e. whether the approaching vessel is under command, restricted in her ability to maneuver or unaware of the danger. Initially, contact would be established by radio or other suitable means. If these fails preventative action would be taken by the vessel to avoid collision. This may include disconnecting the riser and attempting a move-off.

If move off is unsuccessful, collision with the drillship could impact hull tanks containing diesel or base oil. The potential for ignition exists although the high flash point of diesel and the base oil reduce the likelihood of a fire. The main damage from this event is likely to be environmental and asset related. The severity of the environmental damage depends on the inventory of oil onboard the drillship.

Based on work by Amdahl and Kavlie on the design of tankers as cited in the QRA, a maximum of 20% of the merchant vessel collisions more than 100MJ are assumed to result in total loss of the vessel due to severe structure damage, capsize, and/or foundering.

- Probability of Head-On collision = 0.6
- Probability of Total Collapse = 0.2

- Probability of severe heel given collision but no capsize = 0.2

The personnel risk has been calculated based on the frequency of impairment of the main safety functions. For events that cause a total collapse, 50% of the personnel are expected to end up in the sea, while 50% will evacuate via TEMPSC. This number assumes that an evacuation is not carried out every time it is needed. Where a strong collision occurs and only moderate damage is sustained, evacuation is considered to be carried out by TEMPSC. For all other collisions, no evacuation is considered.

For environmental releases, the significant consequence assumed following total collapse is based on the inventory of fuel oil onboard the drillship.

### 9.6.7 Structural failure

Structural failures are only likely to result in fatalities if they require evacuation actions to be taken. This is only likely if the drillship either founders or capsizes, or in the event that listing should be so severe that capsize appears likely. Such events are normally considered to only occur in moderate or severe weather. In these conditions, evacuation is hazardous.

The probability of personnel becoming fatalities during evacuation in moderate or severe weather depends strongly on the means available for evacuation and on the time available before capsize occurs. Rapid capsize in a few minutes would result in all persons entering the sea and a high number of fatalities. Capsize in about 30 minutes would allow evacuation by TEMPSC.

Any event which results in capsize is likely to result in severe environmental damage.

### 9.6.8 Reduction in stability

As stated above, a reduction in stability could lead to foundering or capsize with consequent loss of life, loss of assets and environmental damage.

For events resulting in rapid foundering and/or capsize, it is likely that all personnel will end up in the sea since there will not be time to evacuate using the TEMPSCs. Such events are considered to occur only in severe weather. The chance of rescue and recovery in such cases is assessed to be low.

### 9.6.9 Loss of position

Following a loss of positioning incident, an attempt would be made to close the BOP and disconnect the riser. If this action succeeds, i.e. closure of the BOP and riser disconnection, it is assumed that there will be no significant damage to the well where the disconnected riser impacts the seabed.

When a loss of position occurs, two possible situations could arise:

- A successful disconnection from the BOP: If a disconnection of the riser is successful, there will be no damage except if the riser hits the bottom.
- a failure to disconnect - if disconnection is not successful, it has been assumed that the riser will part and the BOP will close

It is not expected that loss of station keeping will result in loss of life or impairment of safety functions, as the seaworthiness of the vessel will not be affected. In the unlikely event that loss of position leads to a well release or blowout (e.g. if the BOP fails to close) this is included under the relevant event.

Failure to close the BOP and failure to disconnect from the BOP is mainly caused by either,

- LMRP connector failure.
- Shear-ram failure / disabled shear-ram.
- BOP control system failure.
- Operator failure.

The Offshore Reliability Database (OREDA) gives an on-demand failure rate of LMRP connectors of 2E-02 per operation. OREDA also gives failure rates for shear-rams, with a shear-ram failure implying that the shear-ram does not respond and fails to cut the drill string. The shear-ram failure rate is less than 1E-03 per operation. Further, from OREDA, an on-demand failure rate for the BOP control system is expected to be less than 1E-03 per operation.

A fail-safe system is incorporated in the BOP system. Hence, if a loss-of-position situation occurs when the disconnection button is pressed or the riser is parted before the BOP closes, the BOP will, in most cases, close due to the fail-safe system.

The final cause for unsuccessful disconnection is operator failure. Such failures are difficult to quantify, and a range of different probabilities exists. The probability of operator failure has been assumed to be 1E-02 or 1%. This estimate assumes that the personnel on board the drillship are experienced and is considered conservative. Closure of the BOP and disconnection can be executed separately or by pressing the disconnection button, which initiates a pre-programmed sequence of closing in BOP rams and disconnecting from the well. Based on the above discussion, four possible scenarios may be established, giving typical consequences for a loss of position incident.

The consequences due to loss of position have been represented by the event tree (Figure 9-7).

| Frequency of loss of position | Probability of drive-off / drift-off or excursion | Probability of BOP failure | Probability of LMRP failure / operator failure | Event Frequency | Description                                                                                       |

Figure 9-7: Consequences of Loss of Position

Loss of station-keeping ability will most likely result in severe material / economic damage if the BOP fails to close or the LMRP disconnects. A failure to close the BOP will result in severe environmental damage. Otherwise, a loss-of-position event will have negligible environmental consequences.

### 9.6.10 Dropped objects

Dropped loads may impact anywhere within the lifting pattern of the drillship cranes. Should the impact energy of a dropped load exceed the design capacity of the deck, the dropped object might penetrate the deck, resulting in damage on lower deck levels. The greatest risk to personnel is being hit or struck by a falling or swinging object.

Based on the analysis of dropped objects, 0.58% of incidents involving dropped objects resulted in fatalities. 0.58% of the predicted dropped loads on the installation are therefore assumed to result in fatalities.

As to the actual number of fatalities, it is assessed that a dropped load from a crane or other lifting device or from a boom fall, if it results in fatalities, will result in the death of 1 person. For dropped loads from the drilling derrick, a dropped load which results in fatalities is assumed to result in two deaths. The drill floor area is more congested and has a higher manning level, and therefore, there is a greater potential for fatalities than elsewhere. Fatalities are expected to occur predominantly among the operational and maintenance worker groups.

Dropped objects on the drill floor, for instance, from the tubular handling system, may cause a well control problem should critical equipment be damaged. The likelihood of this occurring is considered very low, given the design and high level of automation of the drillship's tubular-handling system. However, the recessed setback area has been identified as an area requiring particular attention during the design and definition of the dimensioning of accidental loads.

The probability of safety functions being impaired by dropped objects is expected to be negligible. This is based on the assumed design requirements imposed on the drillship, most importantly, the requirement to have a high degree of redundancy in primary and support systems, and that there will be no lifting directly over live hydrocarbon-containing equipment.

On offshore facilities dropped objects can result in high economic losses, resulting from a need to stop operations and carry out an investigation to determine root cause of the dropped object incident. Cranes can be classed as unfit for use until they have been inspected and re-certified, thus restricting operations on the drillship. Dropped objects are not considered to cause environmental damage.

## 9.7 Oil spill scenarios

### 9.7.1 Introduction

In addition to the potential impacts on personnel, which, as explained above, are the primary focus of the QRA, major accidents can also affect the environmental and socioeconomic receptors through the potential release of quantities of liquid hydrocarbons to sea. The QRA process has informed a range of credible oil spill cases for which fate and trajectory modelling and impact assessment have been performed. In the

framework of the above, detailed numerical Oil Spill Modelling has been prepared, and the conclusions are presented hereby.

To support the assessment, oil spill modelling was undertaken for an instantaneous surface spill scenario involving Marine Gas Oil (MGO). The scenario represents the loss of containment of 350 m<sup>3</sup> of MGO from a fuel tank onboard a Platform Supply Vessel supporting the drilling campaign. Following incorporation of the project-specific E-SID barrier, this surface spill has been adopted as the representative accidental release scenario for ESIA purposes. The assessment considered the temporal and three-dimensional evolution, transport, weathering and fate of the released MGO on the sea surface, within the water column and at the shoreline.

As mentioned in Chapter 6 as well as in the ALARP section of the present chapter, for the Asopus-1 campaign, Energean will deploy the K-BOS Emergency Shut-In Device (E-SID) as a pre-positioned subsea shut-in device installed between the wellhead and the Stena DrillMAX BOP stack. The E-SID provides an additional, independently actuated shear-and-seal capability at the wellhead. The combined BOP and E-SID configuration reduces the estimated probability of an uncontrolled blowout to approximately  $2.08 \times 10^{-8}$  per well. On this basis, a sustained uncontrolled subsea blowout is not considered a credible representative loss-of-containment scenario for the Asopus-1 campaign. Deployment of the pre-positioned E-SID therefore provides a material project-specific risk reduction and supports the demonstration that well-control risks have been reduced to ALARP. Accordingly, the subsea blowout modelling results are not relied upon for the assessment of the representative environmental release in this ESIA chapter. The instantaneous loss of 350 m<sup>3</sup> of MGO from a PSV fuel tank has instead been adopted as the representative accidental release scenario.

This conclusion does not remove the requirement to maintain contingency source-control arrangements, including BOP intervention, well capping, containment and relief-well planning, for emergency preparedness purposes, as well as all emergency response measures to be in place as per industry standards and legal requirements.

The oil spill modelling was developed in two stages. The first stage consisted of analysing the meteorological and hydrodynamic characteristics of the region, focusing on the environmental parameters that influence oil fate and trajectory. The second stage comprised oil spill simulations performed at the release location for two representative seasonal periods defined according to the prevailing metocean conditions in the study area.

The assumed spill location is approximately 44.3 km (23.9 nautical miles) offshore Othoni Island, approximately 3.2 km (1.7 nautical miles) from the Italian Exclusive Economic Zone (EEZ), and in water depths of approximately 840 m. Along the continental slope of the Ionian Sea, surface and subsurface circulation is primarily influenced by the Atlantic-Ionian Stream and by semi-permanent cyclonic and anticyclonic gyres. Near the spill location, current directions may vary considerably due to interactions between these circulation features and water mass exchanges through the Strait of Otranto. The regional meteorological regime is characterized by the seasonal influence of the Azores High, resulting in predominantly northwesterly winds during spring and summer, and by enhanced cyclonic activity during autumn and winter, when stronger and more variable winds may occur.

The seasonal classification adopted in this study reflects the annual variability of these metocean systems. Season 1 corresponds to the period from October to March, while Season 2 covers the period from April to September. Season 1 is characterized by stronger winds, predominantly from the north, with additional

influence from southerly and southwesterly sectors. Season 1 is within the proposed drilling window for Asopus-1.

Season 2 was modelled as a sensitivity case to test the influence of alternative metocean conditions on spill behaviour. In Season 2, northerly and northwesterly winds remain predominant but generally occur with lower intensities. Surface currents near the spill location are predominantly directed towards the west and southwest throughout the year. The Season 1 stochastic results from the primary risk-envelope basis for assessment of the proposed drilling period. The deterministic simulations presented later in this chapter were selected from the Season 2 stochastic simulation set and are retained only as supplementary sensitivity illustrations of specific spill trajectories under alternative seasonal conditions.

### 9.7.2 Oil spill modelling

The following modelling results represent the unmitigated transport and fate of the released MGO and do not account for oil-spill detection, containment, recovery or other response measures.

Simulations included a 30-day monitoring period following the release. Surface oil drift occurs in all directions during both seasons, with no significant seasonal differences due to the rapid evaporation and degradation characteristics of the product. Areas with the highest probabilities of occurrence are concentrated southwest of the spill location, primarily influenced by northerly winds and westward-to-northwestward surface currents.

Probabilities of occurrence greater than 90% remain restricted to approximately 2 km from the spill location. For the proposed drilling period represented by Season 1, the model indicates that oil may travel up to approximately 122 km within six days. However, this outer extent is associated with the lowest probability of occurrence and should not be interpreted as the expected or high-probability spill footprint. Natural oil dispersion within the water column may extend beyond the area affected at the sea surface, primarily within the upper 0–2 m layer.

For the proposed drilling season (Season 1), the highest shoreline contact probability is observed in Italy, reaching approximately 5%, with a minimum shoreline arrival time of approximately 2.8 days, assuming no oil spill response is undertaken. Sensitivity modelling undertaken for Season 2 identified higher probabilities of shoreline contact under alternative metocean conditions.

For Season 1, the dominant oil fate processes after 30 days are dispersion within the water column (approximately 55%), evaporation (approximately 30%) and biodegradation (approximately 11%-12%). Less than 0.05% of the released oil remains at the sea surface by the end of the simulation period.

Two deterministic sensitivity simulations were selected from the Season 2 stochastic simulation set, representing the shortest shoreline-arrival time and the maximum oil mass reaching the shoreline identified during Season 2. Both sensitivity simulations predicted contact with Othoni Island, Greece, within approximately 2–3 days. No surface oil thickness above the adopted 0.3 µm threshold was predicted after approximately 10 days. Evaporation accounted for approximately 56–60% of the released mass, while oil stranded on the shoreline accounted for approximately 0.4% in the Minimum Arrival Time case and 5.2% in the Maximum Mass on Shore case.

The deterministic simulations provide supplementary information on specific spill trajectories under alternative seasonal metocean conditions. They are not representative deterministic simulations of the

proposed February/March drilling period and do not replace the Season 1 stochastic results as the primary basis for the ESIA assessment.

It should be noted that oil spill model results do not account for the effects of spill response and clean-up operations on oil fate and trajectory. While these models provide a valuable planning and assessment tool by indicating the potential behaviour and extent of an unmitigated spill, they represent a conservative scenario rather than a prediction of actual spill outcomes. In the event of a real incident, response operations would influence the trajectory, persistence, and extent of oiling. Consequently, modelled results are unlikely to be fully representative of a real spill incident and should be interpreted as indicative rather than predictive.

### 9.7.3 Study area

#### 9.7.3.1 Well location

As presented earlier in the study, Block 2 is located on the continental slope off western Greece and eastern Italy, with water depths ranging from 150 m to 3,000 m. The operational area lies approximately 44.3 km (23.9 nautical miles) offshore Othoni Island, approximately 3.2 km (1.7 nautical miles) from the Italian EEZ and in water depths of approximately 840 m. The location and geographical coordinates of the release point are presented below:

Figure 9-8: Location used in oil spill modelling

Table 9-19: Coordinates and water depth at the release site considered in the modelling. Datum WGS84

| RELEASE SITE | LONGITUDE       | LATITUDE        | DEPTH (M) |
|--------------|-----------------|-----------------|-----------|
| Asopus-1     | 18° 57' 28.51"E | 39° 37' 25.92"N | 840       |

### 9.7.3.2 Metocean Conditions

The atmospheric circulation over the Central Mediterranean, where the spill site is located, is controlled by the interaction between subtropical high-pressure systems, mid-latitude cyclones, and the complex topography surrounding the basin (Lionello et al., 2006; Xoplaki et al., 2004). The Ionian Sea, located between southern Italy and western Greece, lies in a transitional zone between the subtropical circulation of North Africa and the mid-latitude atmospheric systems moving across Europe. As a result, the region experiences marked seasonal variability in both wind intensity and direction (Lionello et al., 2006).

During spring and summer, the eastward extension of the Azores High dominates the atmospheric circulation over the Mediterranean Basin (Mariotti and Dell'Aquila, 2012). This large-scale anticyclonic system promotes stable weather conditions, reduced cloud cover, and relatively weak pressure gradients. Under these conditions, northerly to northwesterly winds become prevalent over the study area, particularly evident from May to September, driven by the pressure gradient between the subtropical high-pressure belt and lower-pressure systems over the eastern Mediterranean and Middle East (Xoplaki et al., 2004). Wind speeds are generally lower across the basin during this period, typically around 4.5 m/s, although stronger winds persist over regions such as the Aegean Sea and the Gulf of Lion.

Source: Soukissian & Sotiriou, 2022

Figure 9-9: Mean monthly wind speed and direction for May, August, September and December

From autumn to winter, the atmospheric regime undergoes a substantial transition. The weakening and southward retreat of the subtropical high-pressure systems allow the increased penetration of mid-latitude disturbances into the Mediterranean. At the same time, the southward displacement of the Polar Front Jet enhances cyclonic activity throughout the basin (Lionello et al., 2006). Numerous Mediterranean cyclones develop over the Gulf of Genoa, Adriatic Sea and Tyrrhenian Sea. These low-pressure systems generate stronger and more variable winds, with rapid changes in direction and intensity associated with frontal passages (Xoplaki et al., 2004; Burlando et al., 2009). Regional wind systems such as the warm

southeasterly Sirocco and the cold northeasterly Bora may further modulate the local wind field during this period.

This seasonal transition is reflected in the wind climatology in Figure 9-9. From November to April, higher wind speeds are observed throughout the Mediterranean Basin, reaching their maximum values during winter, particularly in February. During this period, average wind speeds over most of the basin are around 7 m/s, with the highest values occurring in the Aegean Sea and the Gulf of Lion. This period broadly overlaps the proposed Asopus-1 drilling window and therefore represents the representative metocean conditions used for the primary spill assessment.

In contrast, from May to September, wind speeds decrease considerably across the basin, although relatively stronger winds remain in these same regions. October represents a transition month, when wind speeds begin to increase again throughout the Mediterranean, marking the onset of the winter circulation regime.

The seasonal variability of the wind regime plays a major role in controlling the ocean circulation of the Mediterranean. At the basin scale, the Mediterranean circulation is anti-estuarine, with relatively fresh Atlantic Water entering through the Strait of Gibraltar and flowing eastward across the Mediterranean surface layer (Pinardi and Masetti, 2000).

In the Central Mediterranean, the eastward flow of Atlantic Water forms the Atlantic-Ionian Stream (AIS; Figure 9-10: 5b), which enters the Ionian Sea through the Strait of Sicily and constitutes the main surface current connecting the western and eastern Mediterranean basins (Pinardi and Masetti, 2000). Within the Ionian Sea, the interaction between wind forcing, bathymetry, and density gradients generates a complex circulation pattern characterized by semi-permanent cyclonic and anticyclonic gyres, including the Western Ionian Gyre and the Pelops Gyre. These structures promote recirculation and influence the transport pathways of surface waters throughout the basin. The Ionian circulation is closely connected to the Adriatic Sea through the Strait of Otranto. In the Adriatic, a dominant cyclonic circulation is observed, with northward flow along the eastern coast and southward flow along the Italian coast through the Western Adriatic Coastal Current (Figure 9-10: 15). The Southern Adriatic Gyre plays a key role in the exchange of water masses between the Adriatic and Ionian Seas, contributing to the regional circulation and transport processes (Pinardi and Masetti, 2000).

Figure 9-10: Map of main surface currents and gyres in the Mediterranean Sea. Dashed arrows represent summer circulation, plain arrows represent winter circulation. (1) Western Alborán gyre; (2) Ligurian-Provençal current; (3) Lions Gyre; (4) Thyrrenian cyclonic circulation with summer weakening and eastern anticyclone; (5a) Algerian current and eddies, (5b) Atlantic Ionian stream and (5c) mid-Mediterranean jet; (6) Rhodes gyres; (7) Western Cretan gyre; (8) Western Ionian gyre; (9) Gulf of Sirte anticyclone; (10) Shikmona and Mers a-Matruh gyres; (11) Sicilian and Asia Minor current; (12) Iera-Petra gyre; (13) Pelops gyre; (14) Southern Adriatic gyre; (15) Western Adriatic coastal current.

## 9.7.4 Material and method

### 9.7.4.1 Model presentation

OSCAR (Oil Spill Contingency and Response) is a model developed by SINTEF for simulating oil spill fate at sea. It evaluates the transport, weathering and fate of oil at the sea surface, within the water column and along shorelines.

The underlying modelling study included both a subsea blowout case and an instantaneous 350 m<sup>3</sup> MGO surface-spill scenario. Only the MGO surface-spill scenario is presented and relied upon in this ESIA chapter as the representative environmental release scenario.

Currents and winds are input as time-varying grids generated by oceanographic and atmospheric models. OSCAR supports both deterministic and stochastic simulations. Deterministic simulations represent spill behaviour over a specified time period, while stochastic modelling combines multiple simulations under different wind and current conditions to generate probabilistic outputs for oil transport and fate.

### 9.7.4.2 Stochastic approach

In the stochastic approach, several deterministic simulations are performed, considering all the weathering processes, in different scenarios of currents and winds, i.e., the stochastic approach investigates the behaviour of the oil under the influence of an extensive combination of environmental scenarios and determines the statistics (probability, time of arrival, etc.) in each model domain region. Figure 9-11 illustrates how a stochastic outcome (d) is calculated from n deterministic cases (trajectories 1, 2, 3 and 4). The stochastic model results are of great importance because they illustrate both the extent of the area possibly affected by the release and the minimum arrival time of the pollutant at each location with the probability of that location being reached, as well as identifying the regions with higher probability of being reached in different scenarios.

**Figure 9-11: Examples of four individual spill trajectories for a generic release scenario (left panel). Hundreds of individual trajectories overlap each other, as shown at right to calculate stochastic results (probability, minimum arrival times, maximum mass of stranded oil at the coast, etc.)**

### 9.7.4.3 Deterministic approach

Once the stochastic simulations had been completed, two deterministic sensitivity simulations were selected for the 350 m<sup>3</sup> MGO surface-spill scenario. These represented the Minimum Arrival Time to Shore and Maximum Mass on Shore cases identified within the Season 2 stochastic simulation set. The deterministic simulations are retained as supplementary sensitivity cases and do not replace the Season 1 stochastic results as the primary assessment basis.

Oil weathering and fate are presented for each deterministic sensitivity simulation through time-series graphs and mass-balance tables.

## 9.7.5 Scenario parameters

The simulations were performed considering marine gas oil for the surface release. For the surface spill, an instantaneous release of 2,201 bbl (350 m<sup>3</sup>) was considered. This scenario represents a loss of containment from a fuel tank onboard a PSV operating in support of the drilling campaign and has been adopted as the representative accidental release scenario for ESIA purposes.

## 9.7.6 Modelling parameters

### 9.7.6.1 OSCAR model parameters

OSCAR model parameters used in the study are presented in Table 9-20. In the OSCAR model, up to 30,000 particles can be used to represent the undissolved fraction of the oil and another 30,000 to represent the dissolved fraction. In the present study, it was chosen to use 20,000 for each type, totaling 40,000 particles.

This value was defined based on sensitivity tests with successive increases in the number of particles, which showed that results remain unchanged from 10,000 particles onward (5,000 undissolved and 5,000 dissolved). The distribution of particle diameters and masses is handled internally by the OSCAR model.

**Table 9-20: OSCAR model parameters used in the study**

| Model parameters                                     |                                             |                |             |
|------------------------------------------------------|---------------------------------------------|----------------|-------------|
| Particles number                                     | Non-dissolved                               | 20,000         |             |
|                                                      | Dissolved                                   | 20,000         |             |
| Grid Dimensions                                      | Zonal                                       | 2,000          | km          |
|                                                      | Meridional                                  | 1,800          | km          |
| Grid Resolution                                      | X direction (longitude)                     | 2,000          | m           |
|                                                      | Y direction (latitude)                      | 2,000          | m           |
|                                                      | Z direction (depth)<br>(first layer/others) | 2/10 (surface) | m           |
| Depth for concentration grid                         | Min:                                        | 0              | m           |
|                                                      | Max:                                        | 202 (surface)  | m           |
| Dissolved concentration threshold<br>in water column |                                             | 0.058          | ppm         |
| Time step                                            | Model calculation                           | 15             | min         |
|                                                      | Output                                      | 60             | min         |
| Simulation duration                                  | Surface                                     | 30             | days        |
| Number of simulations in stochastic<br>model         |                                             | 500            | Each season |

Table 9-21 presents the oil properties used in the simulations for the surface spill. A marine gas oil (MGO) is expected, and the MGO 500 PPM oil from the OSCAR database was selected as a representative case.

**Table 9-21: Characteristics of the oil used in the simulations**

| Oil Properties | Marine Gas Oil |                   |
|----------------|----------------|-------------------|
| Parameter      | Value          | Unity             |
| Spec. Gravity  | 0.852          | g/cm <sup>3</sup> |
| Viscosity      | 6 (@ 10°C)     | cP                |
| Pour point     | -36            | °C                |
| Wax Content    | 0.81           | %                 |
| Asphaltenes    | 0.02           | %                 |

### 9.7.6.2 Environmental data

The temperature and salinity profile data used in the modelling are presented in Figure 9-12. Data from the CMEMS (Copernicus Marine Environment Monitoring Service) model were used, with seasonal variations considered.

**Figure 9-12: Temperature and salinity profiles in the water column at the release site for each season: Season 1, from October to March; and Season 2 from April to September.**

### 9.7.6.3 Metocean data set

To represent the metocean conditions in the study area, ocean current fields were obtained from the Copernicus Marine Service Mediterranean Sea Physics Analysis and Forecast product (Copernicus Marine Service - CMEMS), which provides hydrodynamic data at a horizontal resolution of  $1/24^\circ$  and a temporal resolution of 3 h. Wind data were obtained from the ERA5 (ECMWF Reanalysis v5) atmospheric reanalysis produced by the European Centre for Medium-Range Weather Forecasts (ECMWF). ERA5 provides globally consistent meteorological fields with an hourly temporal resolution and a horizontal resolution of approximately 0.25.

#### 9.7.6.3.1 Winds

As described (Section 9.7.3.2), the study area is directly influenced by the seasonal atmospheric variability of the Central Mediterranean, resulting from the interaction between the Azores High during the warm season and the increased cyclonic activity associated with mid-latitude disturbances during the cold season. Consequently, two representative seasons were defined for the oil spill simulations:

- Season 1 (October to March): corresponds to the winter circulation regime, characterized by stronger and more variable winds, enhanced cyclonic activity, and average wind speeds around 7 m/s across much of the Mediterranean Basin.
- Season 2 (April to September): represents the summer circulation regime, dominated by the eastward

expansion of the Azores High, resulting in more stable atmospheric conditions, prevailing north-westerly winds over the Ionian Sea, and lower average wind speeds, typically around 4.5 m/s.

As the planned Asopus-1 drilling campaign is expected to occur during Season 1, the Season 1 results are used as the primary basis for interpretation of spill behaviour, while Season 2 is retained as a sensitivity case.

From the ERA5 (ECMWF) data, wind diagrams for each month from 2021 to 2025 are presented in Figure 9-13. Also, Table 9-22 below shows the occurrence of wind direction, while Table 9-23 shows the occurrence of wind intensity. Finally, Figure 9-14 presents the wind diagrams for each season. It is observed that the prevailing winds in both seasons are from NNW. In Season 2 (April to September) wind speeds are about 2 - 6 m/s, whereas Season 1 (October to March) shows a greater occurrence of higher wind speeds, above 6 m/s and a greater contribution of winds from the N.

**Source: ERA5 (ECMWF)**

**Figure 9-13: Wind diagrams at the release site for each month, from 2021 to 2025**

**Table 9-22: Occurrence of wind direction (%) at the release site for each month, from 2021 to 2025**

| DIRECTION | MONTHS |       |       |       |       |       |       |       |       |       |       |       |

#### 9.7.6.3.2 Currents

From the CMEMS data, current diagrams for each month from 2021 to 2025 are presented in Figure 9-15. Table 9-24 shows the occurrence of current direction. Table 9-25 shows the occurrence of current intensity.

At the release point, currents during the representative Season 1 period are predominantly directed towards the west (W) and west-southwest (WSW), with most occurrences showing intensities between 0.1 and 0.2 m/s. Season 2 results are presented as a sensitivity case.

#### 9.7.6.4 Description of grids

For the representative MGO surface-spill modelling, a regular grid was used with a spatial resolution of 2 km in the zonal and meridional directions and a vertical resolution of 10 m. An additional 2 m top layer was included to estimate the concentration of dispersed oil near the surface, following the standard configuration of the OSCAR model. The model grid extends from 8°02'E to 30°47'E in the zonal direction and from 29°46'N to 45°56'N in the meridional direction.

### 9.7.6.5 Bathymetry

The bathymetry used for oil spill modelling is from GEBCO (General Bathymetry Chart of the Oceans) with 30 seconds resolution, the same used for hydrodynamic modeling. Figure 9-16 presents the bathymetry input to the OSCAR model.

Figure 9-16: Bathymetry from GEBCO30" in the OSCAR grid

### 9.7.6.6 Coast classification

The oil-shoreline interactions in the OSCAR model are dependent on both the type of oil considered in the modelling and the type of shoreline. The type of shoreline considered will determine the highest oil-holding capacity at the model's grid points representing the shoreline.

For the study, a Global CoastLine Dataset (GCL\_FCS30) with a detailed classification system (Zuo et al., 2025) was used. The GCL\_FCS30 features a 30 m resolution and was developed using long-term Landsat imagery on the Google Earth Engine (GEE) platform. It is an open-access global coastline category dataset that covers high latitudes in a continuous, smooth line-vector format.

For the broader modelling domain, five coastline categories were represented within the shoreline classification dataset (Figure 9-17):

- Rocky shore;
- Sandy beach;
- Sheltered artificial structure;
- Tidal flat;
- Mangrove / Marsh / Vegetated river mouth.

Source data: Zuo et al., 2025

Figure 9-17: Coast types considered for the simulations

#### 9.7.6.7 Thresholds used in the model

The thresholds used in modelling were:

- Surface: a threshold of 0.3  $\mu\text{m}$  oil thickness was adopted, corresponding to oil with a rainbow sheen appearance resulting from light interference at the oil–air and oil–water interfaces, as defined by the Bonn Agreement Oil Appearance Code (BAOAC). This threshold was selected as a conservative value below the thickness associated with a lethal dose to exposed wildlife (10  $\mu\text{m}$ ), according to French McCay (2009).
- Water column: a threshold of 0.058 ppm was used based on the Norwegian Oil Industry Association (OLF, 2008) guideline for assessing the risk of acute oil pollution effects on fish. The value corresponds to the acute exposure threshold proposed by Neilson et al. (2005, as cited in OLF, 2008) for various aquatic species exposed to dispersed oil.
- Shoreline oiling: a threshold of 1  $\text{g}/\text{m}^2$  was adopted to identify coastal segments affected by stranded oil. This value represents the lower limit commonly associated with recreational restrictions and cleanup activities and has been used to quantify shoreline oiling above levels of concern for socioeconomic and

environmental receptors (National Oceanic and Atmospheric Administration, 2013; Owens and Sergy, 2000).

#### 9.7.6.8 Modelling limitations

Numerical models are tools that aim to represent the dynamics and processes involved in the object of study through mathematical equations and parametrizations. Models generate results that are approximations of the real state and have limitations and errors inherent to the method (e.g., truncation error, approximation error and parameterization of unresolvable physical processes). All these sources contribute to divergences between the real and simulated state of the ocean. Despite all the uncertainties, the model and the approach used are widely accepted internationally (see for instance: Keramea et al., 2021) and the results generated can satisfactorily describe the hydrodynamics and processes of dispersion of constituents when evaluated by different sources of data collected in the domain.

In studies of hydrodynamic modelling and oil dispersion, it is necessary that the study meets specific requirements:

- that it has sufficient domain so that the oil does not leave its limits (or that if it does, it must be with very low probability values);
- have spatial and temporal resolution capable of resolving features and phenomena of different scales;
- have a three-dimensional representation of oil in the marine environment, solve the transport and dispersion of oil on the surface, in droplets and dissolved in water, and solve all the oil weathering processes;
- that the number of oil dispersion modelling simulations represents the environmental variability of the study region.

Thus, assumptions are necessary so that the computational effort in the representation of phenomena at different scales in the results of each study is evaluated so that all these requirements can be met. The interpretation of the results must be done in the light of these adopted assumptions and model uncertainties.

The grid resolution of the hydrodynamic model can directly influence the resolution adopted in the oil transport and dispersion model, since the advection and diffusion calculations rely on hydrodynamic variables – such as currents – provided by the hydrodynamic simulation. As a result, the spatial accuracy of the oil model is inherently constrained by the resolution of the underlying hydrodynamic fields, limiting its ability to adequately represent small-scale coastal processes, such as recirculation zones, tidally induced currents in shallow areas, and local interactions with seabed topography.

It is important to note that the hydrodynamic datasets used in this study were obtained from internationally recognised regional modelling products (CMEMS and ERA5) and were not subject to project-specific calibration using local in situ measurements at the release location. While this may limit the representation of certain fine-scale local processes, the datasets are widely used for regional-scale oil spill modelling and are considered appropriate for assessment of spill transport and fate at the scale of the present study.

## 9.7.7 Modelling results

Stochastic results were based on 500 individual simulations for Season 1 (October–March) and Season 2 (April–September), distributed between 2020 and 2024 (inclusive), totalling 1,000 simulations. Each of these individual trajectories considers different environmental conditions (currents and winds) and all the trajectories corresponding to one scenario are aggregated to form stochastic results maps.

The following maps relating to the stochastic results are presented:

- Probability of oil on the sea surface – These maps define the area on the sea surface and the associated probability in which oiling is expected to exceed the threshold of 0.3  $\mu\text{m}$ .
- Minimum arrival time at surface – These maps define the area on the sea surface and the associated minimum arrival time in which oiling is expected to exceed the threshold of 0.3  $\mu\text{m}$ .
- Probability of oil in the water column – These maps define the area and the associated probability of having concentrations greater than 0.058 ppm. Three maps and two images of the vertical latitudinal profile of oil were presented. One map presented is the maximum probability of water-column oil concentrations exceeding 0.058 ppm, another map of probability of contamination in layers of interest and a third map of oil concentration. The layer was chosen after analyzing the vertical profile of dissolved oil concentrations and include the near-surface layer (approximately 2 m below the surface) below the surface.
- Probability of oil at shore – These maps show the maximum probability at shore where oil exceeds the threshold of 1  $\text{g}/\text{m}^2$ , as defined for each modelling grid point (Section 9.7.6.7).
- Minimum arrival time at shore – These show the minimum arrival time at shore which oiling is expected to exceed the threshold of 1  $\text{g}/\text{m}^2$ .

The selection strategy for the deterministic scenarios was based on the most critical conditions identified in the stochastic simulations, specifically those presenting the shortest oil arrival time and the greatest oil mass reaching the coastline.

### 9.7.7.1 Stochastic Simulation

This section presents the stochastic modelling results for the representative 350  $\text{m}^3$  MGO surface-spill scenario for both Season 1 and Season 2. Season 1 corresponds to the proposed drilling window and is therefore the primary basis for interpretation, while Season 2 is retained as a sensitivity case. Results are presented for the sea surface, water column and shoreline, together with the associated mass balance. The underlying modelling study also included a subsea blowout case. Those results are not presented or relied upon in this chapter because the sustained uncontrolled subsea blowout is not adopted as the representative environmental release scenario for the ESIA following incorporation of the project-specific E-SID barrier.

Unless otherwise stated, the modelling results presented below represent the unmitigated transport and fate of the released MGO and do not account for oil spill detection, containment, recovery or other response measures. The results therefore provide the basis for impact assessment and emergency-response planning rather than a prediction of residual impacts following implementation of the project's oil spill response arrangements.

In the instantaneous surface spill scenario of Marine Gas Oil (MGO), considering a total release volume of 350 m<sup>3</sup>, surface oil drift can be observed in all directions from the spill location in both seasons. This behavior reflects the regional circulation pattern, which includes both northward and southward flows relative to the release point. No significant differences are observed between the two seasons, as MGO is a light refined product and the release is instantaneous, resulting in rapid weathering and evaporation. In both seasons, the areas with the highest probabilities of oil occurrence (>30%) are predominantly located southwest of the spill location, mainly influenced by the prevailing northerly winds and the westward and northwestward surface currents.

At the sea surface, the area with a probability of oil occurrence greater than 90% remains restricted to approximately 2 km from the release location in both seasons. For probabilities greater than 30%, the maximum extent is approximately 4 km in Season 1 and 8 km in Season 2.

Under the representative Season 1 conditions, the maximum modelled surface extent reaches approximately 122 km within six days; however, this outer extent is associated with the lowest probability of occurrence and should not be interpreted as the expected or high-probability spill footprint. The corresponding Season 2 sensitivity result reaches approximately 166 km within nine days. Within the first 72 hours, the maximum modelled surface extent is approximately 100 km in Season 1 and 89 km in Season 2, again corresponding to the outer, low-probability extent of the modelled trajectories.

Within the water column, the modelled area in Season 1 extends beyond the surface footprint, primarily within the upper 0–2 m layer. The maximum modelled extent reaches approximately 150 km from the release location, but this outer extent is associated with probabilities below 5%. Areas with probabilities greater than 30% extend to approximately 12.5 km from the release location in Season 1. The corresponding Season 2 sensitivity results extend to approximately 134 km at low probability and approximately 11.2 km at probabilities greater than 30%.

Oil concentrations above the threshold of 0.058 ppm are identified from the surface down to approximately 60 m in Season 1 and 45 m in Season 2. Higher concentrations (0.45 ppm) are observed down to approximately 30 m depth, following the same pattern in both seasons. The maximum concentrations recorded were 1.19 ppm in Season 1 and 1.041 ppm in Season 2, occurring at depths of approximately 10–20 m in both seasons.

In both seasons, the highest shoreline oiling probability occurs in Italy, reaching 5% in Season 1 and 12.2% in Season 2. The minimum travel time is also recorded in Italy during Season 1, at 2.8 days, whereas in Season 2 the shortest travel time is observed in Greece, at 2.2 days.

Regarding weathering processes after 30 days of simulation, the dominant fate process in Season 1 is oil dispersed within the water column, with a median value of 55%, followed by evaporation, with a median of 30%. In Season 2, oil dispersed within the water column and evaporation are also the dominant processes, with median values of 43% and 42%, respectively. Biodegraded oil is 11–12 % in both seasons. By the end of the 30-day simulation period, the maximum amount of stranded oil reaches 3.0% in Season 1 and 22.1% in Season 2, while less than 0.05% of the released oil remains at the sea surface in both seasons.

#### 9.7.7.4 Shoreline Results

For each season, the highest shoreline-contact probability (Figure 9-25) and shortest shoreline-arrival time (Figure 9-26) are identified in Table 9-26.

Season 1 corresponds to the proposed drilling period, while Season 2 is presented as a sensitivity case.

### 9.7.7.5 Mass Balance

Figure 9-27 presents the modelled mass balance for the instantaneous surface MGO spill scenario for Season 1 and Season 2. The boxplots illustrate the predicted distribution of the released MGO among the main fate categories, including oil remaining on the sea surface, oil dispersed in the water column, evaporation, biodegradation, sedimentation and shoreline stranding. The figure therefore provides an overview of how the spill is expected to weather and redistribute over the simulation period under the two seasonal metocean conditions.

Figure 9-27: Mass balance boxplot for surface MGO Spill, Season 1 (left) and Season 2 (right)

### 9.7.7.6 Season 2 Deterministic Simulation

This section presents two deterministic sensitivity simulations for the 350 m<sup>3</sup> MGO surface-spill scenario. The simulations were selected from the Season 2 stochastic simulation set and represent: (i) the shortest time to shoreline contact identified during Season 2; and (ii) the highest mass of oil reaching the shoreline identified during Season 2.

Season 1 corresponds to the proposed drilling period and remains the primary basis for the ESIA assessment through the Season 1 stochastic results presented in Section 9.7.7.1. The deterministic Season 2

simulations are retained to illustrate specific spill trajectories and oil-fate behaviour under alternative seasonal metocean conditions. They are not representative deterministic simulations of the proposed February/March drilling period.

Unless otherwise stated, the deterministic simulations represent the unmitigated transport and fate of the released MGO and do not account for spill detection, containment, recovery or other response measures. The results therefore illustrate potential spill behaviour in the absence of intervention and should not be interpreted as predictions of residual impacts following implementation of the project's oil-spill response arrangements.

Table 9-27 presents the start dates of the two Season 2 deterministic sensitivity simulations.

**Table 9-27: Start dates of the deterministic Season 2 sensitivity simulations for the 350 m<sup>3</sup> MGO surface spill**

| DETERMINISTIC SENSITIVITY SCENARIO | SIMULATION START DATE |
|------------------------------------|-----------------------|
| Minimum Arrival Time to Shore      | 25 July 2021, 06:00   |
| Maximum Mass on Shore              | 27 July 2021, 02:00   |

For each deterministic sensitivity simulation, the results include the evolution of surface oil thickness and water-column oil concentration over time, the maximum spatial distribution of surface oil thickness, shoreline oil loading and the overall mass balance. These outputs illustrate the transport and weathering behaviour associated with the two selected Season 2 trajectories.

The two Season 2 deterministic sensitivity simulations produced similar oil-drift patterns and maximum oil-thickness distributions. This similarity is attributed to the rapid weathering characteristics of MGO, the instantaneous nature of the release and the close timing of the selected simulations.

The Season 2 Minimum Arrival Time to Shore sensitivity simulation commenced on 25 July 2021 at 06:00. The Season 2 Maximum Mass on Shore sensitivity simulation commenced on 27 July 2021 at 02:00<sup>59</sup>.

In Figures below, the evolution of oil is presented at 6, 24, 48 and 72 hours after the start of the simulation for the MAT and MM scenarios.

In both Season 2 sensitivity simulations, oil initially drifted north-eastward from the release location and reached Othoni Island, Greece, after approximately 2.25 days in the Minimum Arrival Time case and 2.79 days in the Maximum Mass on Shore case. The model subsequently predicted south-westward transport. In the Minimum Arrival Time case, no additional shoreline contact above the adopted 1 g/m<sup>2</sup> threshold was predicted. In the Maximum Mass on Shore case, additional limited shoreline oiling above the adopted threshold was predicted in areas adjacent to Othoni Island.

No surface oil thickness above the adopted 0.3 µm threshold was predicted after approximately 10 days in either simulation, reflecting the rapid weathering characteristics of MGO.

<sup>59</sup> The start dates correspond to the historical metocean conditions used in the oil spill model for the selected deterministic sensitivity simulations. They were identified from the Season 2 stochastic simulation set as the start times that produced, respectively, the shortest shoreline-arrival time and the highest mass of oil on shore. These dates are therefore modelling reference dates only and do not correspond to the planned timing of the Asopus-1 drilling campaign or to a predicted spill occurrence date.

The maximum surface oil-thickness maps indicate that the highest thicknesses were generally within the 25–50  $\mu\text{m}$  range and were concentrated along the initial northeastward transport pathway and subsequent south-westward drift. In the Minimum Arrival Time sensitivity case, a corridor extending approximately 100 km south-westward from the area of greatest thickness was characterised by lower modelled oil thicknesses ranging from 0.3 to 10  $\mu\text{m}$ . In the Maximum Mass on Shore sensitivity case, this low-thickness corridor extended for less than 50 km.

In the Minimum Arrival Time sensitivity case, the modelled shoreline loading at the reported location increased from approximately 0.001  $\text{kg}/\text{m}^2$  upon initial contact to approximately 0.193  $\text{kg}/\text{m}^2$  by the end of the simulation. In the Maximum Mass on Shore sensitivity case, the corresponding modelled loading increased from approximately 0.004  $\text{kg}/\text{m}^2$  to approximately 2.67  $\text{kg}/\text{m}^2$ .

In the unmitigated Season 2 deterministic sensitivity simulations, the surface oil fraction increased rapidly following the instantaneous release and subsequently decreased through weathering, dispersion and shoreline interaction. No surface oil above the adopted modelling threshold remained after approximately 10 days.

Evaporation accounted for approximately 56–60% of the released mass by the end of the 30-day simulation period. Oil in the water column accounted for approximately 28–31.5%, while biodegradation accounted for approximately 7–8%. Oil stranded on the shoreline represented approximately 0.4% of the released mass in the Minimum Arrival Time case and 5.2% in the Maximum Mass on Shore case. Sedimentation represented less than 1% of the released mass.

These results represent the two selected Season 2 sensitivity trajectories without implementation of spill-response measures. They should therefore not be interpreted as the expected residual consequences of a spill during the proposed February/March drilling period.

For the proposed drilling period, the primary ESIA risk-envelope conclusions remain those derived from the Season 1 stochastic simulations: a maximum shoreline-contact probability of approximately 5% and a minimum shoreline-arrival time of approximately 2.8 days, both associated with Italy. The Season 2 deterministic sensitivity simulations provide supplementary trajectory information but do not replace the Season 1 stochastic assessment basis.

Both deterministic simulations were selected from the Season 2 stochastic simulation set and are retained as sensitivity cases. The Season 1 stochastic results remain the primary basis for the ESIA assessment for the proposed drilling period.

#### 9.7.7.7 Season 2 Minimum Arrival Time Sensitivity Simulation

##### 9.7.7.7.1 Surface Results

The following Figures present the deterministic sensitivity simulation for the Season 2 surface MGO spill scenario associated with the shortest predicted shoreline-arrival time. The Figures show the evolution of the spill at 24, 48 and 72 hours after release, illustrating both surface oil thickness and total oil concentration in the water column.

These outputs provide a time-series indication of the predicted movement, spreading and dispersion of MGO during the early phase of the spill, when response actions would be most critical. Figure 9-32 further presents the maximum surface oil thickness predicted over the simulation, identifying the areas where the highest surface concentrations may occur under this conservative sensitivity case.

**Figure 9-28: Season 2 deterministic sensitivity simulation results for the shortest shoreline-arrival time, six hours after release. Surface oil thickness (left) and total water-column oil concentration (right)**

**Figure 9-29: Season 2 deterministic sensitivity simulation for the shortest shoreline-arrival time, 24 hours after release. Surface oil thickness (left) and total water-column oil concentration (right)**

### 9.7.7.7.2 Shoreline results

Figure 9-33 presents the modelled shoreline oil loading at the end of the Season 2 Minimum Arrival Time sensitivity simulation. The figure identifies the shoreline areas where MGO may strand under this conservative deterministic case and shows the predicted loading in kg/m<sup>2</sup>. It provides an indication of the potential spatial distribution and relative intensity of shoreline contact following the shortest predicted shoreline-arrival scenario.

**Figure 9-33: Modelled shoreline oil loading (kg/m<sup>2</sup>) at the end of the Season 2 Minimum Arrival Time sensitivity simulation**

### 9.7.7.7.3 Mass balance

Figure 9-34 and Table 9-28 present the mass balance and final oil fate for the unmitigated Season 2 Minimum Arrival Time sensitivity simulation for the 350 m<sup>3</sup> surface MGO spill. The majority of the released MGO is predicted to evaporate or disperse into the water column, with approximately 60% evaporated and 31.5% present in the water column. A smaller proportion is predicted to biodegrade, amounting to approximately 7.5%, while only limited quantities are predicted to reach the sediment or shoreline, corresponding to 0.6% and 0.4% respectively. This indicates that, under this deterministic sensitivity case, the fate of MGO is dominated by evaporation and water-column dispersion, with limited shoreline stranding.

Figure 9-34: Mass Balance of the Season 2 Minimum Arrival Time sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill

Table 9-28: Oil fate after 30 days in the unmitigated Season 2 Minimum Arrival Time sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill

| SURFACE |     | EVAPORATED |       | WATER COLUMN |      | DEGRADED |      | SEDIMENT |     | ASHORE |     |
|---------|-----|------------|-------|--------------|------|----------|------|----------|-----|--------|-----|
| (%)     | (t) | (%)        | (t)   | (%)          | (t)  | (%)      | (t)  | (%)      | (t) | (%)    | (t) |
| -       | -   | 60         | 172,8 | 31,5         | 90,8 | 7,5      | 21,6 | 0,6      | 1,6 | 0,4    | 1,1 |

#### 9.7.7.8 Season 2 Maximum Mass on Shore Sensitivity Simulation

The Season 2 Maximum Mass on Shore sensitivity simulation represents the deterministic case that produces the greatest shoreline oil loading for the 350 m<sup>3</sup> surface MGO spill under the Season 2 metocean conditions. The results are presented to illustrate the temporal evolution of the spill, the extent of shoreline contact, and the final distribution of oil among the main fate compartments.

##### 9.7.7.8.1 Surface Results

The following Figures present the modelled spill development during the first 72 hours after release, showing both surface oil thickness and total water-column oil concentration at 6, 24, 48 and 72 hours. These figures illustrate the short-term transport and weathering behaviour of the released MGO.

Maximum Mass on Shore | 2  
Oil Thickness of The Impacted Area (mm)

Figure 9-39: Maximum surface oil thickness ( $\mu\text{m}$ ) predicted in the Season 2 Maximum Mass on Shore sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill

#### 9.7.7.8.2 Shoreline results

Figure 9-40 presents the modelled shoreline oil loading after 30 days and identifies the coastal areas where shoreline contact is predicted to occur under this sensitivity scenario. As this is the maximum-mass-on-shore case, the figure represents the most conservative deterministic estimate of shoreline impact for the Season 2 MGO surface spill.

**Figure 9-40: Modelled shoreline oil loading (kg/m<sup>2</sup>) after 30 days in the Season 2 Maximum Mass on Shore sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill**

### 9.7.7.8.3 Mass balance

Figure 9-41 and Table 9-29 present the mass balance and final oil fate for the unmitigated Season 2 Maximum Mass on Shore sensitivity simulation. After 30 days, only a very small proportion of the released oil is predicted to remain on the sea surface (0.2%, or 0.7 t). The majority of the spill is predicted to evaporate (56.5%, or 162.6 t) or remain dispersed in the water column (28.9%, or 83.3 t), while a smaller proportion is predicted to biodegrade (8.8%, or 25.3 t). Limited quantities are predicted to reach the seabed (0.4%, or 1.3 t), whereas the amount reaching the shoreline is estimated at 5.2% (14.8 t). The results therefore indicate that, even in this conservative shoreline-impact scenario, the behaviour of MGO is still dominated by rapid weathering and dispersion.

**Figure 9-41: Mass Balance of the Season 2 Maximum Mass on Shore sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill**

**Table 9-29: Oil fate after 30 days in the unmitigated Season 2 Maximum Mass on Shore sensitivity simulation for the 350 m<sup>3</sup> MGO surface spill**

| SURFACE |     | EVAPORATED |       | WATER COLUMN |      | DEGRADED |      | SEDIMENT |     | ASHORE |      |
|---------|-----|------------|-------|--------------|------|----------|------|----------|-----|--------|------|
| (%)     | (t) | (%)        | (t)   | (%)          | (t)  | (%)      | (t)  | (%)      | (t) | (%)    | (t)  |
| 0,2     | 0,7 | 56,5       | 162,6 | 28,9         | 83,3 | 8,8      | 25,3 | 0,4      | 1,3 | 5,2    | 14,8 |

### 9.7.8 Conclusions

The oil spill modelling evaluated the unmitigated transport, weathering and fate of an instantaneous release of 350 m<sup>3</sup> of Marine Gas Oil (MGO) from a fuel tank aboard a Platform Supply Vessel supporting the proposed Asopus-1 exploration well. The modelling excludes spill detection, containment, recovery and other response actions.

Season 1, spanning October to March, encompasses the proposed drilling period in February and March, and thus establishes the primary risk envelope for the Environmental and Social Impact Assessment (ESIA). Under Season 1 conditions, the probability of surface oil occurrence exceeding 90% remains confined to approximately 2 km from the release location, while the area with a probability greater than 30% extends to approximately 4 km. The maximum modelled surface extent may reach approximately 122 km within six days; however, this outer extent is associated with the lowest probability category and does not represent the expected or high-probability spill footprint.

For Season 1, the highest modelled shoreline-contact probability is associated with Italy, at approximately 5%, with a minimum shoreline-arrival time of approximately 2.8 days. Lower shoreline-contact probabilities are predicted for Croatia, Montenegro, Albania and Greece. These results reflect conditions without implementation of oil-spill response measures.

After 30 days under Season 1 conditions, approximately 55% of the released MGO is dispersed within the water column, approximately 30% has evaporated and approximately 11–12% has biodegraded. Less than 0.05% remains at the sea surface. These results demonstrate the rapid weathering of MGO but do not preclude temporary surface exposure, water-column exposure or shoreline contact.

Season 2 was modelled as a sensitivity case to assess spill behaviour under alternative seasonal metocean conditions. The two deterministic simulations presented in this chapter (Minimum Arrival Time and Maximum Mass on Shore cases) were selected from the Season 2 stochastic simulation set. Both cases predicted shoreline contact at Othoni Island, Greece, within approximately 2–3 days. Oil stranded on the shoreline accounted for approximately 0.4% of the released mass in the Minimum Arrival Time case and 5.2% in the Maximum Mass on Shore case. After approximately 10 days, no surface oil thickness exceeded the adopted 0.3 µm threshold. These deterministic cases provide supplementary sensitivity information and are not representative of the proposed February/March drilling period. They do not replace the Season 1 stochastic results as the primary basis for the ESIA assessment.

Overall, the modelling indicates that the representative 350 m<sup>3</sup> MGO surface spill would weather rapidly, with the highest-probability surface footprint remaining close to the release location. Nevertheless, the unmitigated modelling predicts the potential for wider surface transport, water-column exposure and shoreline contact, including possible transboundary shoreline contact. The environmental significance of these outcomes is evaluated in the relevant ESIA receptor and impact-assessment sections and cannot be determined from trajectory modelling alone.

The modelling results inform the Project's oil-spill preparedness and response arrangements, including detection, notification, mobilisation, containment, recovery, shoreline-response planning and, where applicable, transboundary communication. As response measures were not included in the modelling, the results represent the unmitigated spill envelope rather than the residual effects expected following implementation of the project's response arrangements.

Separately, although a sustained uncontrolled subsea blowout is not adopted as the representative environmental release scenario for this ESIA, the project shall maintain contingency arrangements for well-source control and emergency response, including BOP intervention, capping, containment, and relief-well planning, in accordance with applicable requirements and project emergency preparedness procedures.

## 9.8 Risk evaluation and measures of risk

The risk evaluation is reported for the following risks measures as below:

- Individual Risk per Annum (IRPA)
- Fatal Accident Rate (FAR)
- Potential Loss of Life (PLL) per year
- Main Safety Function (MSF) Impairment frequency per year.

### 9.8.1 Individual risk per annum

The IRPA and the contribution from each accidental event are shown in Table 9-30, and the graphical illustration of the risk results is provided on the bar chart in Figure 9-42 below,

**Table 9-30: Individual Risk Per Annum (IRPA)**

| RISK CONTRIBUTOR                   | INDIVIDUAL RISK PER ANNUM (/YR) |                |                 |                |                 |                |
|------------------------------------|---------------------------------|----------------|-----------------|----------------|-----------------|----------------|
|                                    | OPERATIONAL                     | % CONTRIBUTION | MAINTENANCE     | % CONTRIBUTION | ACCOMMODATION   | % CONTRIBUTION |
| Blowouts and well releases         | 6.00E-07                        | 1.33%          | 1.66E-08        | 0.04%          | 2.19E-08        | 0.08%          |
| Fire, explosion and toxic releases | 5.97E-08                        | 0.13%          | 3.43E-07        | 0.77%          | 6.02E-08        | 0.23%          |

| Dropped objects                    | 3.38E-06                        | 7.51%          | 3.38E-06        | 7.54%          | -               | 0%             |
| Occupational accidents (ex. DOs)   | 1.63E-05                        | 36.34%         | 1.63E-05        | 36.52%         | 1.23E-06        | 4.76%          |
| Helicopter transport               | 2.08E-05                        | 46.26%         | 2.08E-05        | 46.49%         | 2.08E-05        | 80.28%         |
| Helicopter crash and fire          | -                               | 0%             | 7.46E-08        | 0.17%          | -               | 0%             |
| <b>Total</b>                       | <b>4.50E-05</b>                 | <b>100%</b>    | <b>4.47E-05</b> | <b>100%</b>    | <b>2.59E-05</b> | <b>100%</b>    |

**Note:** The blowout and well-release contributions presented in Table 9-30 are derived from the conservative Stena DrillMAX QRA basis and do not take quantitative credit for the additional risk reduction provided by the project-specific E-SID. The E-SID is therefore additional to the safeguards reflected in the reported personnel-risk results.

The IRPA results are predominantly driven by helicopter transportation risk, which contributes approximately 46% of the calculated individual risk for operational and maintenance personnel and approximately 80% for accommodation personnel. Occupational accidents are the largest onboard contributor for operational and maintenance personnel, while marine events and dropped objects make smaller contributions.

Blowouts, well releases, fires, explosions and toxic releases make a relatively small contribution to the calculated IRPA. These results reflect the frequencies, consequence assumptions, occupancy distributions and credited prevention and mitigation measures adopted in the QRA.

The helicopter contribution is dependent on the assumed number of personnel movements, flight frequency, flight duration and campaign duration. These inputs shall be confirmed against the final campaign logistics plan.

Overall, the calculated individual-risk profile is primarily influenced by helicopter transportation and occupational activities rather than facility-related major accident hazards. The calculated IRPA values remain below the applicable upper tolerability criterion. The project-specific POB, worker-group composition and helicopter-exposure assumptions shall be verified against the final campaign manning, and logistics plans before operations commence.

Figure 9-42: IRPA Distribution between Events and Worker Groups

Figure 9-42 illustrates that helicopter transportation and occupational accidents are the principal contributors to IRPA, followed by marine events and dropped objects.

## 9.8.2 Fatal accident rate

The Fatal Accident Rate (FAR) results, expressed as fatalities per  $10^8$  exposed hours, are presented in Table 9-31 and illustrated in Figure 9-43.

The combined FAR shown in Table 9-31 is dominated by helicopter transportation, which contributes approximately 99.5% of the calculated total. The helicopter transportation FAR is normalised to actual flight exposure hours and is therefore not directly comparable to the facility-related FAR acceptance criterion. Excluding helicopter transportation, the calculated facility related FAR is 2.16 fatalities per 10<sup>8</sup> exposed hours.

**Table 9-31: Fatal Accident Rate (FAR)**

| RISK CONTRIBUTOR                   | FATAL ACCIDENT RATE (PER 10 <sup>8</sup> EXPOSED HOURS) |               |               | AVERAGE FAR (PER 10 <sup>8</sup> EXPOSED HOURS) | % CONTRIBUTION (AVERAGE ONLY) |
|------------------------------------|---------------------------------------------------------|---------------|---------------|-------------------------------------------------|-------------------------------|
|                                    | OPERATIONAL                                             | MAINTENANCE   | ACCOMMODATION |                                                 |                               |
| Blowouts and well releases         | 0.07                                                    | 0.00          | 0.00          | 0.07                                            | 0.02%                         |
| Fire, explosion and toxic releases | 0.01                                                    | 0.04          | 0.01          | 0.02                                            | 0.00%                         |
| Marine events                      | 0.45                                                    | 0.45          | 0.45          | 0.45                                            | 0.11%                         |
| Dropped objects                    | 0.40                                                    | 0.40          | -             | 0.27                                            | 0.06%                         |
| Occupational accidents (ex. DOs)   | 1.95                                                    | 1.95          | 0.15          | 1.35                                            | 0.32%                         |
| Travel accidents                   | 416.00                                                  | 416.00        | 416.00        | 416.00                                          | 99.48%                        |
| Helicopter crash and fire          | 0.00                                                    | 0.01          | 0.00          | 0.00                                            | 0.00%                         |
| <b>Total</b>                       | <b>418.88</b>                                           | <b>418.85</b> | <b>416.61</b> | <b>418.16</b>                                   | <b>100%</b>                   |

*Note: The helicopter transportation FAR is calculated using actual flight-exposure hours and is presented separately from the facility-related FAR. The applicable FAR acceptance criterion is assessed against the facility related FAR of 2.16 fatalities per 10<sup>8</sup> exposed hours. The blowout and well-release contributions retain the conservative Stena DrillMAX QRA basis and do not take quantitative credit for the additional project-specific E-SID risk reduction.*

The combined FAR is dominated by helicopter transport because the travel FAR is normalised to actual flight-exposure hours. This differs from the exposure basis used for facility-related hazards, so the combined FAR of 418.16 fatalities per 10<sup>8</sup> exposed hours should not be compared directly with the facility-related FAR acceptance criterion.

Excluding helicopter transport, the calculated facility related FAR is 2.16 fatalities per 10<sup>8</sup> exposed hours. This is below the Stena DrillMAX base-case QRA value of 2.35 and the project acceptance criterion of 10 fatalities per 10<sup>8</sup> exposed hours. Therefore, the facility-related FAR acceptance criterion is met.

Occupational accidents are the largest contributor to the facility related FAR, followed by marine events and dropped objects. Blowouts, well releases, fires, explosions and toxic releases make a comparatively small contribution to the facility-related FAR. These results reflect the event frequencies, consequence assumptions, occupancy distributions and credited prevention and mitigation measures used in the QRA.

The helicopter transportation FAR is sensitive to the assumed number of personnel movements, flight frequency, flight duration and campaign duration. These inputs shall be verified against the final campaign manning and logistics plans before operations commence..

Figure 9-43 presents the distribution of facility related FAR excluding helicopter transportation. Occupational accidents are the principal contributor, followed by marine events and dropped objects.

Figure 9-43: FAR Distribution between Events and Worker Groups (excl. Helicopter Travel)

### 9.8.3 Potential Loss of Life (PLL)

PLL is a measure of the number of fatalities in a year due to workers' exposure to accidental events. The PLL is presented for immediate event (i.e. personnel caught up by the immediate effect of the incident or while attempting to muster) and EER fatalities (i.e. personnel killed while trying to evacuate or escape from the incident).

PLL and graphical representation of PLL results are shown in Table 9-32 and Figure 9-44, respectively.

It should be noted that PLL results reflect the personnel numbers, worker-group distribution, helicopter movements and campaign duration assumed in the QRA. These inputs shall be verified against the final campaign manning, and logistics plans before operations commence.

The blowout and well-release contribution retains the conservative Stena DrillMAX QRA basis and does not take quantitative credit for the additional project-specific E-SID risk reduction. In reality the specific PLL value from blowouts and well releases will be significantly reduced, by implementing the ALARP measure of E-SID inclusion in the project design.

Table 9-32: PLL (Fatalities Per Year)

| RISK CONTRIBUTOR                    | POTENTIAL LOSS OF LIFE (PLL) (FATALITIES PER YEAR) |            |          | % CONTRIBUTION |
|-------------------------------------|----------------------------------------------------|------------|----------|----------------|
|                                     | IMMEDIATE AND MUSTER                               | EVACUATION | TOTAL    |                |
| Blowouts and well releases          | 3.13E-05                                           | 7.05E-06   | 3.83E-05 | 0.65%          |
| Fire & Explosion and toxic releases | 2.14E-05                                           | 2.33E-09   | 2.14E-05 | 0.36%          |

| RISK CONTRIBUTOR                 | POTENTIAL LOSS OF LIFE (PLL) (FATALITIES PER YEAR) |                 |                 | % CONTRIBUTION |
|----------------------------------|----------------------------------------------------|-----------------|-----------------|----------------|
|                                  | IMMEDIATE AND MUSTER                               | EVACUATION      | TOTAL           |                |
| Marine Event                     | -                                                  | 1.37E-03        | 1.37E-03        | 23.10%         |
| Dropped objects                  | 3.38E-04                                           | -               | 3.38E-04        | 5.70%          |
| Occupational accidents (ex. DOs) | 1.66E-03                                           | -               | 1.66E-03        | 27.99%         |
| Travel accidents                 | 2.50E-03                                           | -               | 2.50E-03        | 42.16%         |
| Helicopter crash and fire        | 3.73E-06                                           | -               | 3.73E-06        | 0.06%          |
| <b>Total</b>                     | <b>4.55E-03</b>                                    | <b>1.37E-03</b> | <b>5.93E-03</b> | <b>100%</b>    |

The overall Potential Loss of Life (PLL) is 5.93E-03 fatalities per year. The largest contributors are travel accidents (approximately 42.2%), followed by occupational accidents (approximately 28.0%) and marine events (approximately 23.1%). Together, these account for approximately 93% of the total PLL, indicating that travel and workplace safety activities dominate the overall risk profile. Dropped objects contribute 5.70%, while major accident hazards such as blowouts and well releases (0.65%) and fire, explosion, and toxic releases (0.36%) make relatively minor contributions.

The results indicate that the principal contributors to PLL are travel accidents, occupational accidents and marine events. Continued attention to these risk drivers, together with maintenance of existing process safety barriers and emergency response arrangements, remains important to ensure risks remain ALARP.

Figure 9-44: PLL Distribution between Events

## 9.8.4 Main Safety Function (MSF) impairment

Table 9-33 shows the frequency with which accidental events will result in loss or impairment of the main safety functions per year, and the graphical representation of the impairment frequencies is shown in Figure 9-45.

**Table 9-33: Main Safety Function Impairment Per Year**

| RISK CONTRIBUTOR                   | IMPAIRMENT FREQUENCY (/YR) |                    |                      |                 | % CONTRIBUTION (TR ONLY) |
|------------------------------------|----------------------------|--------------------|----------------------|-----------------|--------------------------|
|                                    | ESCAPE ROUTES              | EVACUATION SYSTEMS | STRUCTURAL INTEGRITY | TR              |                          |
| Blowouts and well releases         | 3.47E-08                   | 3.47E-08           | -                    | 1.78E-07        | 17.00%                   |
| Fire, explosion and toxic releases | 8.87E-09                   | 1.63E-08           | -                    | 1.98E-09        | 0.19%                    |
| Helicopter crash and fire          | -                          | -                  | -                    | 8.69E-07        | 82.81%                   |
| Ship collision                     | 2.78E-07                   | 2.78E-07           | 2.78E-07             | -               | 0%                       |
| Structural failure                 | 2.65E-06                   | 2.65E-06           | 2.65E-06             | -               | 0%                       |
| Reduction in stability             | 6.02E-06                   | 6.02E-06           | 6.02E-06             | -               | 0%                       |
| <b>Total</b>                       | <b>8.99E-06</b>            | <b>9.00E-06</b>    | <b>8.95E-06</b>      | <b>1.05E-06</b> | <b>100%</b>              |

**Note:** The blowout and well-release impairment frequencies retain the conservative Stena DrillMAX QRA basis and do not take quantitative credit for the additional project-specific E-SID risk reduction. In reality, the specific PLL value from blowouts and well releases will be significantly reduced, by implementing the ALARP measure of E-SID inclusion in the project design.

The calculated Temporary Refuge (TR) impairment frequency is dominated by helicopter crash and fire events, which account for approximately 82.8% of the total. Blowouts and well releases contribute approximately 17.0%, while fire, explosion and toxic release events contribute approximately 0.2%. These percentages apply only to TR impairment, not to the impairment of other main safety functions or to the overall project risk.

Reductions in stability and structural failure are the principal contributors to impairment of escape routes, evacuation systems and structural integrity, followed by ship collision. These events do not contribute directly to the calculated TR impairment frequency. All calculated impairment frequencies remain below the applicable acceptance criteria.

The highest total impairment frequency is associated with evacuation systems, at 9.00E-06 per year. This remains below the total impairment criterion of 5.0E-04 per year. Each individual accidental-event contribution also remains below the applicable criterion of 1.0E-04 per year per accidental load.

Figure 9-45: MSFs Impairment Frequency per year

## 9.8.5 Assessment against risk acceptance criteria

### 9.8.5.1 Personnel risk

The overall IRPA for the most exposed worker group is  $4.5\text{E-}05$  per year. This is significantly below the HEREMA upper tolerability limit of  $1\text{E-}03$  per year and therefore satisfies the individual risk acceptance criterion.

Excluding helicopter transportation risk, the facility-related FAR associated with the Asopus-1 drilling campaign is 2.16 fatalities per  $10^8$  exposed hours, which is below the FAR acceptance criterion of 10 fatalities per  $10^8$  exposed hours. The FAR acceptance criterion is therefore met.

A comparison of FAR levels reported for offshore operations in the UK and Norway shows no consistent overall trend. Globally, FAR levels in Europe are generally at the lower end of the observed range and are broadly comparable with those reported in Canada, the USA and Australia.

### 9.8.5.2 Main safety function integrity

All Main Safety Function impairment frequencies are below the applicable acceptance criteria. The highest impairment frequency is associated with the evacuation systems at  $9.0\text{E-}06$  per year, which is well below the criteria of  $1.0\text{E-}04$  per year for individual accidental loads and  $5.0\text{E-}04$  per year in total.

### 9.8.5.3 TR Integrity

The calculated TR/LQ impairment frequency for Asopus-1 is 1.05E-06 per year, which is below the applicable Main Safety Function acceptance criteria of 1.0E-04 per year for each individual accidental load and 5.0E-04 per year in total. This demonstrates compliance with the applicable TR/LQ integrity criteria.

## 9.9 Uncertainty and limitations

The main uncertainties relevant to the assessment are summarised below. These uncertainties do not invalidate risk assessment, but they define the basis on which the results should be interpreted and identify the assumptions that should be verified before operations commence.

- Statistical uncertainty in data sources - The risks have been calculated using some industry generic data from the QRA as a basis. The databases reflect the industry's experience over many years of exposure. As typical MODUs are designed not to suffer catastrophic failure, the failure data population is generally small, introducing a degree of uncertainty.
- Applicability of the data sources and models to the MODU - The data sources for the assessment have been selected from marine experience and offshore experience as appropriate. The drillship was built and is maintained in accordance with classification rules common to other MODUs. Existing databases representing good practice are appropriate for assessing hazards for which there is broad experience, including most of those considered.
- Uncertainty in assumptions with respect to the operating conditions - The QRA assessment is based on pre-drill estimates and available geological and geophysical information at the time of assessment. As the Asopus-1 well has not yet been drilled, actual subsurface conditions, including reservoir characteristics, formation pressures and fluid properties, may differ from those assumed. The assessment therefore incorporates conservative assumptions where appropriate and should be reviewed if material new information becomes available during well planning or operations.
- The IRPA, PLL and helicopter transportation results depend on the assumed POB, worker-group distribution, personnel movements, flight frequency, flight duration and campaign duration. These assumptions shall be verified against the final campaign manning, and logistics plans before operations commence. Where the final assumptions differ materially from those used in the QRA, the affected risk results shall be reviewed and updated.

The QRA developed through an integrated modelling approach is subject to limitations arising from the assumptions, simplifications, and uncertainties inherent in the modelling techniques used. The assessment relies on available operational information, which may not fully reflect actual operating conditions. Furthermore, the complex interactions between hazards and emergency response effectiveness cannot be fully represented within the integrated modelling approach adopted for the assessment.

Model predictions should be regarded as indicative of potential spill behaviour rather than forecasts of actual outcomes. Importantly, oil spill models typically do not account for the effects of response and clean-up operations, such as containment, recovery, dispersant use, or shoreline protection measures, which can substantially reduce the extent and persistence of oil contamination. Consequently, while modelling provides a valuable tool for risk assessment, contingency planning, and understanding potential environmental

consequences, the results are unlikely to be fully representative of a real spill incident and should be interpreted within the context of these inherent uncertainties and conservative assumptions.

## 9.10 Dimensioning accidental loads assessment

As per the existing Stena DRILLMAX QRA, a specific explosion analysis was carried out in the design risk assessment for the moonpool, drill floor and shaker house areas to calculate maximum explosion overpressures and pulse durations for these areas. The following categories are used to define the accidental loads,

- Fire and explosion loads.
- Impact loads including dropped object, helicopter impact, and ship collision loads.
- Extreme weather and unintended flooding loads.

### 9.10.1 Fire and explosion loads

The governing fire and explosion loads considered in the assessment are associated with blowout scenarios. Loads from machinery space and TR fires are not explicitly calculated in this assessment. The COMEX programme is used to estimate the maximum explosion overpressures in the QRA assessment. Thereafter, if necessary for the case considered, the program NVBANG Version 3 was used to consider the effect of a different gas, such as methane, possible walls being released during the explosion and venting of burnt gas at an early stage of the explosion.

The duration of the overpressure is calculated by using the program NVBANG. The COMEX programme was also used to assess the impact on the TR module aft wall. Explosion overpressures are calculated for a stoichiometric propane mixture. This represents the worst-case leak composition for hydrocarbon mixtures likely to be encountered.

#### 9.10.1.1 Blowout fire

##### 9.10.1.1.1 Temporary refuge

These conservative blowout loads are retained as the DrillMAX design accidental-load basis for personnel and structural safety and are separate from the representative environmental release scenario adopted for the ESIA.

As per NMA regulation, “Exterior faces of accommodation spaces and control stations facing the drilling or production area shall at least be insulated to A60 standard. Based on the results of risk analyses/calculation of design fire, class H fire divisions may be required”.

As per PSA Facilities regulations, “TR outer walls facing a processing or drilling area and which may be exposed to fire from these shall be H60 if there is potential for heat loads greater than 100 kW/m<sup>2</sup> and all other outer walls shall be A60”.

It has been identified that no events would result in an impinging fire or a heat load exceeding 100 kW/m<sup>2</sup> on the external TR bulkheads. Therefore, A60-rated bulkheads would survive for at least 1 hour and are consequently considered sufficient. The backup DP room windows should be suitably rated to withstand the impact of an explosion from the drill floor, moonpool or shale shaker areas.

#### 9.10.1.1.2 Drill Floor and Derrick Structure

The drill tower structure could be exposed to heat fluxes ranging from 200 kW/m<sup>2</sup> to 300 kW/m<sup>2</sup> in the event of an ignited blowout. NORSOK S-001 and OS-A101 both specify a value of 250 kW/m<sup>2</sup>. If the move-off after a blowout is successful, the above heat loads would last at most 5 minutes. The likelihood of an ignited blowout in which move-off is unsuccessful is assessed as considerably lower than 1E-04 per year and is therefore not considered a governing Design Accidental Load (DAL) scenario. The design explosion overpressure is calculated to be 5 kPa (0.05 bar) combined with a pulse duration of 0.19 s.

The worst-case scenario is expected to be an explosion with ignition near the floor in the middle of the drill floor area (Figure 9-46), with an approximate volume of 4200 m<sup>3</sup>. The area is moderately congested, and the equipment is mainly placed near the floor. The area is partly open on the forward or aft side through one of the pipe-entering doors. With the only cladding along the edges, upward venting is very large. The twin drill tower and haulage devices also block the upward venting. Downward explosion venting is prevented by the solid drill floor. The total explosion-venting area of approximately 700 m<sup>2</sup> is extremely large for this size. Most of the walls comprise light cladding panels that are expected to fail at approximately 10 kPa (0.1 barg), thereby providing explosion venting.

The maximum explosion overpressure is expected to be 5 kPa (0.05 barg) when the area is 100% filled with a stoichiometric mixture of air and propane. The overpressure pulse is shown in Figure 9-47. For input to a structural response assessment in the area, the explosion impulse could be adequately modelled as a triangular pulse with a duration of 190 milliseconds.

The graph displays the pressure response of the Drillfloor over time. The y-axis represents Pressure in kPa, ranging from 0 to 5. The x-axis represents Time in seconds, ranging from 0 to 0.8. The pressure is stable at zero until approximately 0.55 seconds, after which it begins to rise. It reaches a peak of approximately 4.8 kPa at 0.78 seconds and then drops sharply to zero.

| Time (s) | Pressure (kPa) |
|----------|----------------|
| 0.0      | 0.0            |
| 0.1      | 0.0            |
| 0.2      | 0.0            |
| 0.3      | 0.0            |
| 0.4      | 0.0            |
| 0.5      | 0.0            |
| 0.55     | 0.0            |
| 0.6      | 0.2            |
| 0.65     | 0.5            |
| 0.7      | 1.0            |
| 0.75     | 2.5            |
| 0.78     | 4.8            |
| 0.8      | 0.0            |

### 9.10.1.1.3 Moonpool

In the event of an ignited blowout below the drill floor, the moonpool area (Figure 9-48) could be exposed to heat fluxes ranging from 200 kW/m<sup>2</sup> to 300 kW/m<sup>2</sup>. The port crane pedestal could also be exposed to this heat load if it is impinged by a jet fire. As for drill floor blowouts, if move-off is successful, the above heat loads would last at most 5 minutes. The worst-case explosion scenario is expected to be an ignition near the starboard wall in this large area, with a volume of approximately 42 000 m<sup>3</sup>. The area does not have much congestion, and the equipment is mainly placed on the upper deck and down in the moonpool near the boundaries. The pipe stand in this area is assumed to be 1/3 full, which increases congestion. The area is partly open on all sides except forward. Downward explosion venting is not possible through the moonpool. The total explosion-venting area of approximately 2900 m<sup>2</sup> is extremely large for this size. Some areas of the upper deck are fitted with light cladding panels that are expected to fail at approximately 10 kPa

overpressures, thereby providing explosion venting. Their weight is assumed to be 21 kg/m<sup>2</sup>. The clad area is assessed to be 170 m<sup>2</sup>.

Figure 9-48: Moonpool Area Layout

The maximum explosion overpressure is expected to be 40 kPa (0.4 barg) when the area is 100% filled with a stoichiometric mixture of air and propane. The overpressure pulse is shown in Figure 9-49. For input to a structural response assessment in the area, the explosion impulse could be adequately modelled as a triangular pulse with a duration of 170 milliseconds. The pressure will be spread forward towards the TR. The explosion in the moonpool area covers a large volume, and the pressure on the aft TR module wall is expected to be the same as in the moonpool area: 40 kPa (0.4 barg) for 130 milliseconds. A triangular pressure pulse shape can be used. The aft TR wall may experience local damage if exposed to this overpressure. However, the SDL assessment concluded that the bulkhead maintains its structural integrity and can withstand the design explosion load.

Figure 9-49: Moonpool Area - Pressure Vs Time Profile

#### 9.10.1.1.4 Shale shaker house

In the event of an ignited blowout in the shale shaker room (Figure 9-50), the entire room would be engulfed with flames and subjected to heat fluxes ranging from 200 kW/m<sup>2</sup> to 300 kW/m<sup>2</sup>. As for drill floor blowouts, if move-off is successful, the above heat loads would last at most 5 minutes.

The worst-case explosion scenario is expected to involve ignition near the starboard wall of this medium-sized area, with an approximate volume of 1200 m<sup>3</sup>. The area contains 4 shale shakers, desilter, degasser and some tanks. The area is relatively congested and almost closed in all directions, with only the mechanical ventilation system open to the surroundings. An access ladder and some small openings down to the area below give a small venting possibility downwards. The total explosion-venting area is extremely small for an area this size. The room has 3 doors and some walls that are expected to open up in the explosion. They are assumed to weigh 30 kg/m<sup>2</sup> and start opening at an overpressure of 200 kPa (2 barg).

The maximum explosion overpressure is expected to be 220 kPa (2.2 barg) when the area is 100% filled with a stoichiometric mixture of air and propane. The overpressure pulse is shown in Figure 9-51. For input to a structural response assessment in the area, the explosion impulse could be adequately modelled as a triangular pulse with a duration of 600 milliseconds.

Figure 9-51: Shale Shaker – Pressure Vs Time Profile

## 9.10.2 Impact loads

### 9.10.2.1 Dropped objects

In the context of dropped objects, critical areas typically include TR, workshops, storage areas for pressurised gas and hydrocarbon equipment. Identified critical areas for the MODU include,

- TR, wheelhouse, control room, and backup DP room.
- Switch / transformer room above the mud pits / mud pumps.
- Subsea control area, HPU area and APV area.
- Setback area.
- Fuel oil storage tank and adjacent void spaces (protection provided by plated deck above).
- Engine rooms and engine control room.

### 9.10.2.2 Helicopter impact

The helideck is located forward on a platform at deck 12 above the bridge deck and LQ. It is designed, constructed, and maintained to the requirements of:

- UK Civil Aviation Authority (CAA) CAP 437;
- Norway BSL D5-1; and
- DNV-OS-E401, “Helicopter Decks.

### 9.10.2.3 Ship collision

Collision design accidental loads are represented by a kinetic energy of 11 MJ for bow or stern impacts and 14 MJ for sideways impacts, corresponding to a 5,000-tonne supply vessel travelling at 2 m/s. These values are taken as the minimum credible design cases for supply vessel collisions.

More severe impacts can occur from larger merchant vessels or higher approach speeds. Based on published work on ship collision mechanics, only collisions with energies more than 100 MJ are considered to present a realistic potential for impairment of the drillship's main safety functions. Below this threshold, damage is expected to be limited to localised hull structures and non-critical tanks.

Where collision energies are sufficient to breach hull tanks containing diesel or base oil, the most significant consequence is expected to be environmental release, with a low probability of ignition given the high flash points of these products. In extreme cases where collision energies exceed structural capacity, loss of vessel stability and associated personnel risk cannot be excluded.

### 9.10.3 Extreme weather

A feature of the MODU design is a setback area recessed into the hull that could be flooded in severe weather.

Buoyancy loss and subsequent flooding may result from subsea blowout. For a DP vessel in water depths of at least 250 m (minimum operating water depth for the drillship), the probability of loss of buoyancy or a displacement of significance to the stability is considered to be low as the dynamic forces of a rising gas plume would tend to push the vessel away from the centre of the plume and away from the least buoyant areas. Given the Asopus-1 water depth of approximately 840 m, the loss of buoyancy due to a subsea gas plume is not considered a credible dimensioning accidental event.

The dimensioning accidental loads and design accidental loads are summarised in Table 9-34 and Table 9-35.

**Table 9-34: Dimensioning Accidental Loads**

| DIMENSIONING EVENT                                 | AREA                                          | LOAD                                                                                                    |
|----------------------------------------------------|-----------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Blowout                                            | TR                                            | Less than 100 kW/m <sup>2</sup> for 30 minutes (minimum rating for outer walls A60 as per regulations). |

## 9.11 Escape and evacuation assessment

The philosophy adopted for dimensioning the escape routes is identified in Table 9-36 below,

**Table 9-36: Primary and Secondary Escape Routes**

| DESIGNATION | DEFINITION                                                                                                         |
|-------------|--------------------------------------------------------------------------------------------------------------------|
| Primary     | Escape route from permanently manned areas and intermittently manned areas with higher levels of personnel traffic |
| Secondary   | Escape route from normally unmanned areas and intermittently manned areas with little personnel traffic            |

### 9.11.1 Primary (main) escape routes

The primary escape routes aboard the Stena DrillMax are fully enclosed escape tunnels that run the length of the vessel, one on the port side and one on the starboard side. These tunnels allow personnel to move from aft to the TR whilst protected against the effects of fire and explosion. The portside tunnel has three access points: one aft, one at the accommodation, and one forward of the APV/subsea control areas. The starboard escape tunnel has four access points: one aft, one at the accommodation, one forward of the APV/subsea control areas, and one aft of the setback area adjacent to the upper deck laydown area.

### 9.11.2 Secondary (local) escape routes

#### 9.11.2.1 TR and offices

During an emergency on the vessel, personnel located in the accommodation will have direct access to the muster area in the mess hall on general alarm. In general, personnel can use the central staircase in the accommodation to move between deck levels. To access the lifeboat muster station on deck level 9, personnel must leave the accommodation by the port or starboard external staircase, climb a flight of stairs, and then descend a flight of stairs to reach the walkways to the lifeboats. Personnel could also escape to the aft of the vessel via the internal escape routes along the port and starboard sides.

#### 9.11.2.2 Moonpool area

Personnel can use the escape ways at upper deck level to access the escape tunnels from forward of the subsea control/APV areas (around 20 m forward) or from the access point adjacent to the upper deck laydown area on the starboard side (around 10 m aft).

#### 9.11.2.3 Drill floor and derrick

Personnel can proceed and use the stairways above the mud processing module to descend one flight to deck level 9, where they can access the temporary refuge by walking approximately 35 m along the open deck. If this route is impaired, they may travel rearward to the stairs behind the setback area, where they can descend approximately 25 m to the upper deck level and access the starboard-side escape tunnel adjacent to the laydown area.

#### 9.11.2.4 Mud process module

---

Personnel can use the internal staircase at the aft centre of the mud processing module to descend to upper deck level, where they can access the escape tunnels on either the port or starboard side.

#### 9.11.2.5 Cranes

---

The drillship is equipped with three 85 te deck cranes (1 port and 2 starboard). In addition, there will be a small crane forward for servicing the helideck, and dedicated pipe-handling equipment both forward and aft of the drill tower. Crane operators must descend the stairs from the operator's cabin, then use the escape tunnel access aft of the upper lay down area. An alternative access point is located forward of the subsea control/APV areas.

### 9.11.3 Temporary refuge and muster area

---

The TR and primary muster area are located in the accommodation at the forward of the vessel. The mess hall area on deck level 5 is the proposed muster area. NORSOK S-001 states that all muster areas shall be suitably sized to enable efficient accounting of personnel and donning of personal protective equipment (0.4 m<sup>2</sup> per lifeboat seat).

As the proposed muster area is in the same place for all lifeboats, the required area is 0.35 m<sup>2</sup> per person in line with SOLAS requirements. For a maximum POB of 180, this gives a required area of 63 m<sup>2</sup>. The area of the proposed muster area is 186.7 m<sup>2</sup>, which is sufficient.

The wheelhouse and main control room are located on the top level of the accommodation and normally contain all the necessary command-and-control functions expected in a TR. The backup DP room is also located on the top deck of the accommodation and is protected by A60 bulkheads.

#### 9.11.4 Lifeboat provision

---

The Stena DrillMAX has two 54-man freefall lifeboats positioned forward of the accommodation on the port and starboard side, along with a single 60-man and a single 54-man lifeboat at the aft. The centrally located lifeboats at the aft can contribute to both port and starboard lifeboat provision, providing 100% capacity on both sides in line with SOLAS requirements. The lifeboats can be launched at a heel angle of 20 degrees.

The proposed number and location of lifeboats are considered adequate, as the enclosed primary escape routes along the port and starboard sides of the vessel mean that the probability of anyone being trapped at the aft end of the vessel is considered remote.

If only one side of the drillship lifeboats is available to launch, a total of 108 persons would be able to escape via the forward lifeboats. If one of these lifeboats failed to launch or was out of service for maintenance, then persons would be required to escape via the aft lifeboats.

### 9.11.5 Liferaft provision

The NMA Lifesaving Regulation (section 11) requires that:

1. There shall be sufficient liferaft capacity for the total number of persons on board.
2. The location of the liferafts shall be based on the evacuation analysis (cf. section 5).
3. On ship-shaped units, it shall be possible to evacuate all persons on board using liferafts, even if the liferafts on any one side are lost or unavailable.
4. Where the distance from the extreme end of the stem or stern to the nearest lifeboat or liferaft is more than 100 metres, an extra liferaft shall be arranged at the stem or stern.
5. Liferafts shall be arranged in marine evacuation systems (MES). Alternatively, liferafts may be placed on separate davits, with no more than three liferafts per davit.

Liferafts shall be certified for launch from the relevant heights at the unit's least favourable heel angle. In addition, the PSA facilities regulations state "As means of evacuation in respect of evacuation to sea, free-fall lifeboats supplemented by escape chutes and associated life rafts shall be used." NORSOK S-001 states that "escape chutes with rafts should be used as a secondary means of evacuation in the main evacuation area".

Based on the above, liferafts with a total capacity of 426 (213 port and 213 starboard) are provided; made up of 12 x 35-man liferafts (6 liferafts port forward and 6 liferafts starboard forward) along with one 6-man throw-over liferaft located aft.

There are four liferaft hoists forward, each assigned 3 liferafts. An embarkation ladder is situated beside the liferaft stations on both sides of the vessel. Escape means from the aft is currently provided by the 6-man throwover liferaft and 2 lifebuoys, 1 port and 1 starboard. There are lifebuoys located along the length of the vessel on both port and starboard sides.

### 9.11.6 Escape and evacuation time

The time required for a safe escape and evacuation has been estimated using generic data and the drillship's dimensions and layout. The escape and evacuation process has been divided into steps to aid the time estimation. The worst-case scenario is personnel in the cabin of the riser storage area crane being unable to move forward due to a fire or explosion on the drill floor or moonpool area. This would mean descending the crane ladder to upper deck level at the riser storage area, accessing the enclosed escape tunnel through the starboard entrance slightly forward of the crane to reach the temporary refuge and muster in the mess hall.

The total time to muster and evacuate using lifeboats is estimated to be 15 minutes. This is comparable to the NMA regulation requiring that all persons on board can be evacuated by lifeboats within 15 minutes, regardless of weather conditions. This is measured to the point where lifeboats are launched and released.

This timeline is considered to represent the fastest possible time for an orderly evacuation it is not an evacuation time design basis for the TR. To fully assess an emergency and prevent unnecessary evacuation,

and to execute a full, orderly evacuation, including the rescue of trapped personnel, a 30-minute evacuation time is considered more reasonable.

### 9.11.7 Evacuation and escape fatalities

For a blowout or an impending ship collision the drillship would attempt to move-off location. Evacuation of personnel from the vessel would only be required if move-off was unsuccessful. In the case of the evacuation of non-essential personnel, this will be done by helicopter (if available). Lifeboat evacuation would only be attempted if helicopter evacuation were not possible, either due to the drillship's list or insufficient time.

The probability of successful launch of a free-fall lifeboat has been taken as 95.6%.

The probability of unsuccessful escape via liferafts has been calculated based on the following,

- Personnel end up in water (calm weather) 0.03
- Personnel end up in water (moderate weather) 0.25
- Personnel end up in water (severe weather) 0.50

The probability of successful recovery from the sea to a place of safety is calculated based on estimated recovery and survival times, depending on sea temperature and the type of clothing (assumed to be survival suits and lifejackets) worn. In the event of failed lifeboat or liferaft evacuation, some people are assumed to become immediate fatalities, and some are assumed to enter the water. The liferafts and lifeboats are all supplied with embarkation ladders.

## 9.12 Risk reduction and ALARP demonstration

The hazard identification and risk evaluation process supports the demonstration that all major accident hazards (MAHs) have been identified and understood and are being effectively managed. The risks presented in Section 9.8 measure the risk from identified MAH against defined acceptance criteria and conclude that the risk levels on the MODU are tolerable. Section 9.8 also highlights the main risk contributors, i.e. those hazards that contribute most to the overall risk on the vessel and identifies additional measures capable of reducing the risk from the MAHs.

Each risk reduction option has been assessed for effectiveness and potential benefit. Where a measure is deemed not practicable, the rationale for non-implementation is documented. The SDL Action Register contains identified risk-reduction measures and their implementation status. This register is regarded as a living document and an essential element of the SDL risk management process; thus, it is continuously updated to reflect the current state of all recommended risk-reducing measures.

Project-specific risk reduction measures identified for the Asopus-1 campaign are managed through the applicable drilling, HSE and project assurance processes.

### 9.12.1 Blowouts

Prevention of uncontrolled release of fluid from the well starts with adequate well planning. The primary means of well control is to maintain the primary barrier with suitable hydrostatic pressure through

appropriate drilling fluid density, MPD surface backpressure, and continuous monitoring of parameters to adjust the density as required. Failure of these measures will activate the secondary well control barrier, the blowout preventer (BOP). The well-control strategy incorporates multiple layers of protection, including the primary well barrier, the subsea BOP system and the project-specific E-SID. The E-SID provides an additional independently actuated shear-and-seal capability at the wellhead, supplementing the primary and secondary well-control barriers.

The strategy meets or exceeds applicable class requirements and international codes and is consistent with standard industry practice. It has been evaluated for suitability and is considered adequate for controlling the risk from blowout and well release hazards. The MODU is designed to operate in deep waters with a minimum operating water depth of 250 m, and this exploration well's water depth is 840 m. This reduces the risk to the installation and people on it from shallow gas blowouts.

For the Asopus-1 campaign, Energean will deploy the K-BOS E-SID as a pre-positioned subsea emergency shut-in device installed below the Stena DrillMAX BOP stack. The E-SID provides an additional independent wellhead barrier and helps reduce the likelihood and potential for escalation of loss-of-well-control events.

For the Asopus-1 campaign, Energean will deploy the K-BOS E-SID as a pre-positioned subsea emergency shut-in device installed below the Stena DrillMAX BOP stack. The E-SID provides an additional, independently actuated shear-and-seal capability at the wellhead and reduces the likelihood of escalation following failure of the conventional well-control barriers. The combined BOP and E-SID configuration reduce the estimated probability of an uncontrolled blowout to approximately  $2.08 \times 10^{-8}$  per well. As a project-specific risk-reduction measure, the E-SID provides material additional protection and supports the demonstration that well-control risks have been reduced to ALARP.

## 9.12.2 Mud processing area

### 9.12.2.1 Fire and explosion protection

The shale shaker room, mud pits and mud pump rooms constitute the mud process areas. The shaker room is located forward of the drilling areas while the mud pits and mud pumps are located within the hull of the vessel. The shaker room and mud pits have been identified as areas that are prone to fire and explosion and have been protected accordingly. They are classified as zone 1 (a zone in which an explosive atmosphere is likely to occur during normal operation) hazardous areas and are negatively pressurised via mechanically forced ventilation to prevent build-up of flammable gas.

Detectors are also installed to detect the presence of flammable gas. Fire-fighting in the mud process area is supplied by low-expansion foam, and additional protection is provided by the A60-rated fire wall around the boundaries of the shaker room.

Given the congestion in the shale shaker room, an explosion study was undertaken to evaluate the maximum overpressure. The maximum overpressure was estimated to be 2.2 barg. The potential consequences of the design explosion overpressure have been assessed in the existing Stena DrillMAX design risk assessment. Essential safety systems required following the event are assumed to remain available or to be suitably segregated from the affected area, consistent with the design accidental-load basis.

The quantitative risk analysis has also shown that the contribution of drilling-related fire and explosion hazards to the overall risk profile of the DrillMAX is very low.

#### 9.12.2.2 Operator's cabin zone classification

---

The Operator's Cabin was initially classified as a hazardous area; thus, it was recommended that the necessary design changes be implemented to make it a safe area, including overpressure ventilation. As the entrance door has now been moved to an unclassified area (cement unit), overpressure ventilation inside the cabin is considered unnecessary.

#### 9.12.2.3 CCTV provision in the operator's cabin

---

It was observed that the initial arrangement in the mud process area prevents the operator from seeing the shakers from the cabin. SDL has reviewed the need for a CCTV provision and has now installed one in the shale shaker room. This will facilitate monitoring of the shaker room.

### 9.12.3 Non process fires

#### 9.12.3.1 Engine room protection

---

Although the bulkheads separating the engine rooms are A-60-rated, there was concern about the adequacy of the A-0-rated engine room deck heads. The concern relates to the vulnerability of the engine rooms to fire in the well-test and drill-floor areas.

The risk analysis has quantitatively evaluated the likelihood of a well test and drill floor fire impairing the engine deck head and concluded that the frequency of this event is very low in the order of 10<sup>-5</sup> per year.

#### 9.12.3.2 Gas detectors in the engine and engine room air intakes

---

It was assessed in the risk analysis that a gas release from the well test area could potentially be drawn into the combustion air and engine room air intakes – this is not relevant for Asopus-1 since no well testing is planned. For the MODU, risk is reduced by the current provision of 2 detectors at each air intake.

The engine room ventilation shall shut down automatically when gas is detected in the engine room air intake, while protection against gas ingress through the combustion air is provided by rig savers.

#### 9.12.3.3 Helicopter refuelling area protection

---

The helideck refuelling tank is now located on deck 10 behind a firewall. The area is protected by a deluge system which can be operated remotely. In addition, the Heli guard station has been equipped with CCTV for improved fire monitoring. This provision reduces the likelihood of escalation of a helideck fire.

## 9.12.4 Escape route

### 9.12.4.1 Positive pressurisation

---

The vessel is equipped with enclosed escape tunnels on the port and starboard sides that lead from aft to the accommodation block. HVAC systems comprising supply and exhaust dampers have been installed at the aft and forward port and starboard positions of the escape tunnel. The systems provide the needed pressurisation to prevent the ingress of smoke and gas into the tunnel.

### 9.12.4.2 Additional entrance to the escape tunnel

---

An extra door has been added to the escape tunnel to facilitate escape from the drill floor and thus minimise exposure of people in this area to hazardous events. The initial arrangement would have required personnel to travel a long distance to reach the aft tunnel entrance if the forward one were unavailable.

### 9.12.4.3 Watertight doors obstruction

---

It was observed that installing watertight doors in each escape tunnel would create an obstruction during escape due to the time required to open the hydraulic door manually or remotely. The current philosophy is to keep these doors open unless a visiting vessel is approaching.

## 9.12.5 Contingency source control measures

---

While the QRA shows that a prolonged uncontrolled deepwater blowout is not the environmental assessment scenario for Block 2, maintaining contingency source-control measures remains both an operational requirement and a regulatory expectation, irrespective of the representative environmental assessment scenario adopted for the campaign. This subheading outlines escalation options if the primary well-control barriers fail, highlighting the availability of additional source-control capabilities beyond the installed BOP and E-SID barrier system.

In the unlikely event that the primary and secondary well control barriers fail to achieve shut-in, or well integrity is otherwise compromised, a source control and spill response strategy will be implemented to regain control of the well, minimise the duration of any release, and limit environmental consequences. The response framework comprises rig-based intervention, installed subsea shut-in capability, post-incident source-control measures, and oil spill response arrangements.

The initial response is to use the rig's well control systems, including the subsea BOP and its secondary activation paths, to shut in the well. Where required, the K-BOS E-SID provides an additional pre-installed subsea shut-in capability at the wellhead. If these measures do not achieve full isolation, source control may be escalated to capping, containment and, ultimately, relief well drilling.

These source control measures run alongside the campaign's oil spill response arrangement, covering spill monitoring, offshore response, shoreline protection planning, and coordination with specialist response

resources. Together, the well control, source control, and oil spill response elements form an integrated response framework for managing a loss-of-containment event.

#### 9.12.5.1 BOP intervention – secondary control systems

---

As already described earlier, Stena DrillMAX subsea BOP is the primary mechanical shut-in device upon detection of a kick. It is equipped with a primary subsea control system and diverse backup activation paths. These secondary systems provide independent routes to close critical BOP elements rapidly if the main control system or the drilling unit is compromised.

#### 9.12.5.2 E-SID intervention – backup activation

---

The K-BOS E-SID will be equipped with a secondary acoustic backup system, independent of the primary ROV-driven electrical activation pathway. This system may be operated remotely in the unlikely event that the MODU loses control capabilities. This redundant acoustic channel provides a backup actuation method, enabling authorised personnel at an alternative location to initiate E-SID closure and secure the wellbore.

The E-SID is deployed as a Layer 3 well-control barrier and is independent of the primary BOP control system. Successful activation may contribute to source-control outcomes by limiting or preventing continued release from the well.

#### 9.12.5.3 Well capping

---

Well capping is the primary post-incident source-control measure when rig-based well control and E-SID intervention fail to achieve a full shut-in. A capping stack is a high-pressure isolation device installed on top of a failed BOP, LMRP, or wellhead to stop or significantly restrict well flow while also providing a mechanical interface for any subsequent containment or kill operations.

Energean's Tier 3 oil spill response and source-control capability for this campaign is based on established contractual arrangements and industry mutual-aid mechanisms that provide access to subsea source-control equipment, including capping and containment systems, where required. The scheme provides access to response-ready capping stack systems and subsea incident response toolkits, including 18-3/4-in, 15,000-psi capping stacks stored at strategic bases, with Stavanger, Norway, among the anticipated mobilisation locations for Block 2. The available equipment includes the capping stack itself, together with the ancillary subsea tooling required for survey, BOP intervention, debris clearance and related source control activities.

The feasibility and timing of capping depend on the condition of the incident well and the offshore environment at the time of response. Relevant factors include weather and sea state; the extent of any damage to the wellhead or BOP; the effects of sustained flow on well integrity; access to the well from above; plume behaviour; and the structural capacity of the well/BOP system to withstand the loads imposed during capping. These conditions are evaluated after the incident and used to confirm the capping method, interface configuration and installation sequence.

#### 9.12.5.4 Well containment

Well containment is a secondary source control option used when capping does not fully shut in the well, but a controlled flow path to a surface facility can be established. It involves creating a temporary subsea production system that routes hydrocarbons from the capping stack or wellhead through subsea flowlines and a marine riser to a suitably equipped vessel, where standard well-test equipment processes the fluids and the stabilised liquids are offloaded to a tanker.

Containment necessitates the prior installation and commissioning of the subsea system and the surface processing infrastructure and is therefore regarded as an infrequent fallback measure. It has the potential to mitigate environmental impact by restricting uncontrolled discharges. However, it does not supplant the need for permanent source control through a relief well and abandonment.

#### 9.12.5.5 Relief well drilling

Relief well drilling is the ultimate source control measure for permanently killing and abandoning an incident well. Although capping or containment may temporarily secure the well and reduce environmental impact, permanent abandonment still requires interception of the flowing well and placement of kill fluid and cement into the flow path.

For Asopus 1, a relief well would be planned as a directional well drilled to intercept the original wellbore at a suitable target depth. Once the intercept is achieved, dynamic kill operations would be undertaken by pumping kill fluid from the relief well into the incident well, followed by cementing to permanently seal the well. The detailed kill strategy would depend on the actual incident configuration and would take account of any capping or containment system already in place.

Relief well planning for Block 2 will therefore identify suitable relief well locations, required backup well-construction materials, and potential drilling units capable of operating at the relevant water depth and with the necessary dynamic positioning capability. A relief well may require the mobilisation of an additional suitable rig.

For planning purposes, a conservative relief well duration of approximately 80 days remains appropriate, subject to local conditions, rig availability and the condition of the incident well. This duration reflects the mobilisation of a suitable drilling unit, well design, logistics, drilling operations, interception, kill operations, and contingency allowances. Therefore, it is adopted as a conservative basis for planning and environmental assessment.

### 9.13 Conclusions and recommendations

A quantitative risk assessment has been carried out based on the previously conducted QRA study by DNV for the Stena DrillMAX, which is included in the RoMH submitted to HEREMA (Ref. Number: 36452/14.07.2026).

In this assessment, all credible hazards with the potential to cause a major accident have been identified, and the major accident risks have been evaluated against the applicable risk acceptance criteria and shown to be reduced to a level that is tolerable and as low as reasonably practicable.

The assessment has been carried out in compliance with the applicable Greek Statutory Provisions, guidance, and international industry safety standards. The following sections provide the main conclusions from the results of the risk assessment and the high-level review of the EER provisions.

Conservative blowout scenarios from the existing Stena DrillMAX QRA have been retained for personnel-risk assessment purposes. However, following incorporation of the project-specific K-BOS E-SID barrier, the representative environmental release scenario adopted for the ESIA is the instantaneous loss of 350 m<sup>3</sup> of MGO from a PSV fuel tank.

### 9.13.1 Personnel

The calculated risk levels satisfy the applicable risk acceptance criteria and have been demonstrated to be ALARP.

- The IRPA for each worker group has been calculated against an upper tolerability criterion of 1.0E-03 per year as follows:
  - Operational worker group : 4.50E-05 per year
  - Maintenance worker group : 4.47E-05 per year
  - Accommodation group : 2.59E-05 per year
- Excluding helicopter transportation, the facility related FAR is 2.16 fatalities per 100 million exposed hours, compared with the applicable acceptance criterion of 10 fatalities per 100 million exposed hours. The facility-related FAR acceptance criterion is therefore satisfied.
- Helicopter transportation has been assessed separately using actual flight-exposure hours, resulting in a FAR of 416 fatalities per 100 million flight-exposure hours. Because this value is normalised against actual flight hours rather than the total offshore exposure period, it is not directly comparable with the facility-related FAR acceptance criterion. Helicopter transportation risk is included in the IRPA and PLL results.
- The PLL is calculated to be 5.93E-03 fatalities per year. There is no maximum criterion associated with PLL and it is generally used for risk-benefit comparisons.

### 9.13.2 TR integrity

The frequency of accidental events which result in loss of the TR is 1.05E-06 per year.

- Provided that the credited HVAC isolation, damper sealing and TR integrity measures perform as assumed in the QRA, smoke is not predicted to impair the TR within its 60-minute endurance period.
- The calculated TR impairment frequency remains below the applicable acceptance criterion.

### 9.13.3 Evacuation, escape and rescue (eer)

The EER arrangements on the Stena DrillMAX have been revised in recent years. The capacity of the TEMPSCs has been reduced from 60 to 54 persons, and to compensate, Stena has installed an additional 60-person TEMPSC at the aft of the drillship.

This ensures that full evacuation remains possible if one side of the vessel is impaired.

#### 9.13.4 Comparative analysis

The risks associated with the proposed drilling of a single exploration well for the Asopus-1 project have been evaluated and compared with the base case (4-off HPHT wells) of the existing DrillMAX QRA. The proposed exploration well presents a lower risk profile than the reference case of four HPHT exploration wells per year. The principal reasons are summarised below and reflected in Table 9-37.

- The principal differences arise from the reduced operational scope, i.e., four (4) HPHT wells versus one (1) exploration well.
- Difference between helicopter flight hours and flights over the Asopus-1 drilling campaign period, assumed to be 70 days.
- The base case used a conservative full-flow gas release rate of 260 kg/s, whereas the proposed Asopus well gas release rate is 79 kg/s. The existing DrillMAX consequence basis has been retained as a conservative assessment.

The project-specific assessment produces lower calculated IRPA, PLL and TR impairment frequencies than the existing four-well DrillMAX base case. The differences primarily reflect the reduced operational scope and campaign exposure period, together with the project-specific exposure assumptions used in the assessment. The comparison is therefore a sensitivity comparison and not a like-for-like comparison between identical drilling programmes.

The frequency of accidental events leading to loss of the Temporary Refuge (TR) decreased from 6.77E-06 per year to 1.05E-06 per year, indicating that the proposed activity remains within the established safety basis of the MODU and continues to satisfy the applicable risk acceptance criteria. In addition to the standard well-control barriers provided by the Stena DrillMAX, the Asopus-1 campaign will deploy the K-BOS E-SID as a pre-positioned subsea emergency shut-in device installed below the BOP stack.

The E-SID provides an independent wellhead shear-and-seal barrier, separate from the primary BOP control system. The project-specific probabilistic risk assessment indicates that the combined BOP and E-SID configuration reduces the estimated probability of an uncontrolled blowout to approximately  $2.08 \times 10^{-8}$  per well.

On this basis, a sustained uncontrolled subsea blowout is not considered the representative loss-of-containment scenario for the Asopus-1 campaign. The deployment of the E-SID provides material project-specific risk reduction and supports the demonstration that well-control risks have been reduced to ALARP. Contingency source-control arrangements will nevertheless be maintained for emergency preparedness, including BOP intervention, well capping, containment and relief-well planning.

Overall, the assessment confirms that the proposed Asopus-1 drilling campaign remains within the established safety basis of the Stena DrillMAX and satisfies the applicable risk acceptance criteria.

Compared with the conservative reference HPHT exploration campaign considered in the existing DrillMAX QRA, the Asopus-1 activity results in lower individual risk, lower group risk and lower Main Safety Function impairment frequencies.

Table 9-37: Sensitivity Analysis Comparison

| PARAMETER                                  | BASE CASE – HPHT EXPLORATION CAMPAIGN | PROPOSED EXPLORATION WELL           | COMMENTS                                                                                                                                                                                                |
|--------------------------------------------|---------------------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of wells considered                 | 4 HPHT exploration wells per year     | 1 exploration well per year         | Reduced exposure frequency due to a single well operation, contributing to lower individual and group risk.                                                                                             |
| Water depth                                | 500 - 2,000 m                         | 840 m                               | Asopus-1 is over 500m of water, which is considered deep water and aligns with the basis of the existing QRA. In shallower water, the consequences of subsea blowouts would be more severe.             |
| Blowout flow rate                          | Full flow rate of 260 kg/s            | Oil - 14 kg/sec;<br>Gas – 79 kg/sec | The new case predicts a lower potential for hydrocarbon inventory release than the full-flow rate used in the base case, resulting in reduced consequence severity.                                     |
| Total POB                                  | 180                                   | 60 with a possibility to reach 180  | Total group risk exposure will change with respect to occupancy.                                                                                                                                        |
| Individual Risk Per Annum (IRPA)           | 1.84E-04 per year                     | 4.50E-5 per year                    | Approximately 75% reduction in individual risk.                                                                                                                                                         |
| Potential Loss of Life (PLL)               | 5.26E-02 fatalities/year              | 5.93E-03 fatalities/year            | Approximately 89% lower than the reference-case PLL, based on the project-specific personnel and exposure assumptions used in the QRA. This is a sensitivity comparison and not a like-for-like result. |
| Frequency of loss of Temporary Refuge (TR) | 6.77E-06 per year                     | 1.05E-06 per year                   | Approximately 84% lower than the reference-case TR impairment frequency, reflecting the reduced campaign exposure and project-specific assessment assumptions.                                          |

**Note:** Helicopter transportation FAR has not been included as a comparative metric because the Asopus-1 and existing DrillMAX QRA values use different exposure-normalisation methods. The Asopus-1 value is calculated using actual flight-exposure hours, whereas the existing DrillMAX QRA normalised transportation risk across the total facility exposure period.

The comparison is intended to illustrate the sensitivity of the calculated results to differences in operational scope, campaign duration and assessment assumptions. It is not a like-for-like comparison between identical drilling campaigns. The project-specific POB, worker-group distribution and helicopter-exposure assumptions shall be verified against the final campaign manning, and logistics plans before operations commence, and the affected risk results reviewed if material differences are identified.

# 10 Assessment and Evaluation of environmental impacts

## 10.1 Assessment of potentially significant impacts from normal / routine project activities

The assessment and evaluation of the potentially significant impacts from the implementation of the proposed project were carried out based on the following steps:

- Step 1: Identification and evaluation of the Significant Environmental Parameters (SEPs) or Valued Receptors (VRs) of the natural and anthropogenic environment of the study area.
- Step 2: Assessment and evaluation of the Potential Significant Impacts from routine operations of the mobilisation, drilling, decommissioning/abandonment phases of the examined Project.

### 10.1.1 Impact assessment and evaluation methodology

The Project's potential significant impacts on the natural and anthropogenic environment of the study area are assessed and evaluated, including the use of natural resources, the emission of pollutants, the creation of nuisances, and the disposal of generated waste. The impacts being examined concern all the abiotic and biotic parameters that shape the natural environment (atmosphere, soil, water, flora, fauna, noise, traffic, landscape, etc.), as well as land use and socio-economic characteristics of the study area.

The assessment and evaluation of E&S impacts mainly focus on the characteristics of potentially significant impacts (likelihood of occurrence, extent, intensity, cumulative/synergistic action, etc.) of all activities and individual elements of the project, based on the project design data, supporting studies, the existing environmental conditions and the results of the computational models (atmosphere, noise, etc.) used to simulate the potential impacts on various Environmental Parameters.

Within the framework of the present assessment, the following potential impacts are evaluated:

- Impacts during the Project lifetime, including the preparatory/mobilisation, operation, and demobilisation / decommissioning phases of the Project under study (routine project activities),
- Project's resilience to climate change, that is, its ability to cope with and adapt to the expected climate risks, according to the National Climate Law (Law No. 4936, GG 105/A/27.5.2022)
- Impacts deriving from the vulnerability of the Project to the risks of serious accidents or disasters related to the Project (non-routine operation), according to JMD 1915/2018, are evaluated in Section **Error! Reference source not found.**

#### 10.1.1.1 Recognition and evaluation of significant environmental aspects

The process of **Environmental and Social Impact Assessment (ESIA)** initially requires the distinction of parameters of the natural and anthropogenic environment receiving the impacts, into significant or

noteworthy elements defined as Significant Environmental Parameters (SEPs) or **Valued Receptors-VRs**. As a VR, any element of the natural and anthropogenic environment is characterized as significant by the parties involved in the evaluation, licensing, and implementation process of the project under study (project proponent, competent authorities and services, consultants, other parties directly or indirectly involved or affected by the implementation of the project, etc.).

VRs are categorized considering their environmental value, as derived from the data presented in Chapter 8 of the Current State of the Environment and - where possible - their sensitivity to the Project's activities.

Based on the above, VRs are categorized as **Low, Medium, and High Importance**. The significance of each VR is considered as weight in the final assessment of impacts during the ESIA process, as described in Section 10.1.1.3.2. In this way, the same impact is ultimately assessed as more significant in a High Importance Environmental Parameter compared to a Low Importance Environmental Parameter.

In the next stage of the ESIA process, the significance of each VR is correlated with the inherent significance of the corresponding potential impacts on it, leading to the comprehensive final assessment and evaluation of the expected environmental and social impacts. Based on the assessment of the current environmental conditions of the study area (see Chapter 8), the identified VRs and their corresponding assessment are presented in the following Table.

**Table 10-1: Identification and Assessment of Key Valued Receptors in the Study Area**

| VALUED RECEPTOR (VR)                                          |                                      | VR SIGNIFICANCE | JUSTIFICATION                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------|--------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Climatic and Bioclimatic Characteristics</b>               | Climate, microclimate and bioclimate | Medium          | Climate and weather conditions are important operational receptors that influence drilling safety, vessel movements, helicopter operations, and emergency response planning. However, the temporary offshore drilling campaign is not expected to cause measurable changes to regional climate, microclimate, or bioclimatic conditions.                                                                   |
|                                                               | Climate change                       | High            | Climate change is a highly important environmental receptor due to the contribution of greenhouse gas emissions from MODU, support vessels, and helicopter operations. Although emissions from the Project are temporary and limited in duration, they contribute cumulatively to a global environmental issue of international significance and are therefore considered a very high-importance receptor. |
| <b>Morphological and Topological Characteristics</b>          | Morphology                           | Medium          | Seabed morphology is an important receptor because drilling activities involve direct interaction with the seabed at the well location. However, effects are expected to be highly localized and temporary, with no dredging, reclamation, anchoring system, or permanent alteration of seabed or coastal morphology.                                                                                      |
|                                                               | Landscape                            | Low             | The well location is approximately 44 km offshore and no permanent offshore or onshore structures will be installed. Visual effects associated with the MODU, support vessels, and helicopter movements will be temporary and largely confined to distant offshore views, resulting in limited interaction with landscape receptors.                                                                       |
| <b>Geological, Tectonic and Soil / Seabed Characteristics</b> | Geology and slope stability          | Medium          | The Project involves drilling through geological formations and therefore interacts directly with the subsurface environment; however, effects are highly localized to the well and no significant alteration of regional geological conditions is expected.                                                                                                                                               |
|                                                               | Tectonics and Seismicity             | Medium          | The Project is located within a seismically active region of the eastern Mediterranean, making seismicity an important design and safety consideration, although                                                                                                                                                                                                                                           |

| VALUED RECEPTOR (VR)      |                                                          | VR SIGNIFICANCE | JUSTIFICATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|----------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           |                                                          |                 | drilling activities are not expected to induce significant seismic events.                                                                                                                                                                                                                                                                                                                                                                                                    |
|                           | Soil                                                     | Low             | No terrestrial land take, excavation, or soil disturbance is required, as the Project is entirely offshore and supported by existing infrastructure.                                                                                                                                                                                                                                                                                                                          |
|                           | Seabed                                                   | Medium          | Installation and operation of the well, discharge of permitted drilling-related materials, and presence of the BOP and riser system interact directly with the seabed environment, although effects are expected to be localized and temporary.                                                                                                                                                                                                                               |
| Terrestrial Habitats      | Terrestrial habitats – vegetation                        | Low             | No vegetation clearance, land take, or terrestrial habitat disturbance is required.                                                                                                                                                                                                                                                                                                                                                                                           |
|                           | Terrestrial fauna (excluding avifauna)                   | Low             | No direct interaction with terrestrial fauna is expected due to the absence of new onshore infrastructure.                                                                                                                                                                                                                                                                                                                                                                    |
| Marine Habitats           | Marine habitats – underwater vegetation and flora        | Medium          | Marine habitats constitute a sensitive receptor because drilling activities occur within the marine environment and may result in localized seabed disturbance and temporary changes in water quality.                                                                                                                                                                                                                                                                        |
|                           | Marine fauna                                             | High            | Marine mammals, sea turtles, fish, and other marine species are among the most sensitive receptors potentially interacting with vessel traffic, underwater noise, lighting, and accidental events.                                                                                                                                                                                                                                                                            |
| Avifauna                  | Avifauna                                                 | Medium          | Offshore and migratory bird species may interact with vessel and MODU lighting and helicopter operations; however, effects are expected to be temporary and localized.                                                                                                                                                                                                                                                                                                        |
| Protected Areas           | Protected Areas                                          | High            | The wider study area includes international, European, and national designated sites and protected species, making protected areas a highly sensitive receptor despite the offshore location of the well.                                                                                                                                                                                                                                                                     |
|                           | Forests and wooded areas                                 | Low             | No interaction with forested or wooded environments is anticipated.                                                                                                                                                                                                                                                                                                                                                                                                           |
|                           | Other important natural areas                            | High            | Ecologically important marine and coastal areas occur within the wider region and may support protected species and habitats.                                                                                                                                                                                                                                                                                                                                                 |
| Anthropogenic Environment | Spatial Planning and Land Use                            | Medium          | Block 2 contains no permanent settlements or terrestrial land use, while onshore activities are confined to existing operational facilities at the Port of Igoumenitsa and Corfu International Airport, with no land take or change in land use. However, the Project directly relates to the Regional Spatial Framework for the Ionian Islands, which identifies offshore hydrocarbon exploration as an activity of national importance subject to environmental safeguards. |
|                           | Maritime uses                                            | High            | The wider study area supports intensive maritime uses including commercial shipping, fisheries, submarine cables, aquaculture, tourism and recreational navigation. Shipping and commercial fisheries have the greatest spatial interaction with the Project through the temporary safety exclusion zone and support-vessel movements, making maritime uses a highly important receptor.                                                                                      |
|                           | Structure and Functions of the Anthropogenic Environment | Low             | Project activities are limited to existing port and airport facilities and require no new infrastructure, land take or permanent occupation. Consequently, no fragmentation of settlement structure, urban fabric or existing land use functions is anticipated.                                                                                                                                                                                                              |
|                           | Cultural Heritage                                        | High            | The Project area lies within a region of recognised maritime archaeological importance, and marine surveys have identified a target interpreted as a possible ancient shipwreck (Target T057) within the survey area. Although terrestrial heritage assets lie outside the Project footprint, the potential presence of an underwater cultural heritage asset makes this a highly sensitive receptor requiring avoidance and protection measures.                             |

| VALUED RECEPTOR (VR)                                           |                                                                                        | VR SIGNIFICANCE | JUSTIFICATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Socio-economic environment                                     | Economic Activities                                                                    | High            | The Project interacts with regional economic activities, particularly commercial fisheries, tourism, port services, logistics and local supply chains. The Project also has the potential to contribute positively to the Greek economy through investment, employment, procurement and demand for local and regional goods and services.                                                                                                                                                                                                                                       |
|                                                                | Community H&S                                                                          | High            | Community health and safety is a highly important receptor given the presence of established communities and active transport infrastructure, including the existing airport, port and marine traffic. The Project will interact with these existing transport activities through port logistics, helicopter operations and offshore MODU and support-vessel movements. However, the offshore well site is approximately 44 km from the nearest communities, limiting the potential for direct interaction with the wider community.                                            |
| Social Infrastructure                                          | Social Infrastructure                                                                  | Low             | The Project will use existing health and emergency services only incidentally and does not require new or expanded social infrastructure. Demand on existing service capacity is expected to be negligible.                                                                                                                                                                                                                                                                                                                                                                     |
| Technical Infrastructure                                       | Maritime Infrastructure                                                                | High            | The Project area lies within active offshore navigation routes in the Ionian Sea. Temporary establishment of a 500 m safety zone around the MODU and increased vessel traffic (PSVs) introduce potential interaction with commercial shipping lanes. However, impacts are temporary, locally confined, and managed through maritime safety procedures (NAVTEX, Notices to Mariners, and support vessel support, where available).                                                                                                                                               |
|                                                                | Other transport infrastructures (road, port, airport, logistics corridors)             | Medium          | The Project utilises existing onshore infrastructure including Igoumenitsa Port and Corfu International Airport without requiring new construction or capacity expansion. Interactions are operational and temporary, associated with crew transfers, supply logistics, and mobilisation/demobilisation activities.                                                                                                                                                                                                                                                             |
|                                                                | Energy and telecommunications infrastructure                                           | Low             | The Project utilises existing onshore energy and telecommunications infrastructure, without requiring capacity expansion.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                                | Environmental infrastructure (waste, wastewater, spill response, reception facilities) | Medium          | The Project will not rely on municipal or port-operated waste and wastewater management services for treatment or disposal. Instead, waste requiring transport ashore will be transported directly via the shore base to authorised regional facilities in accordance with the Project Waste Management Plan and applicable national legislation. Wastewater generated onboard the MODU and Project vessels will be managed by the relevant operator in accordance with applicable maritime requirements, vessel-specific systems and the Project's environmental requirements. |
| Atmospheric Environment                                        | Air quality                                                                            | Medium          | Emissions from the MODU, support vessels, and helicopters will occur throughout the drilling campaign and represent one of the principal operational environmental interactions, although effects are expected to be temporary and dispersed offshore.                                                                                                                                                                                                                                                                                                                          |
| Acoustic Environment and Emissions of Vibrations and Radiation | Airborne noise                                                                         | Medium          | Noise will be generated by drilling operations, vessels, and helicopters, but impacts will be temporary and largely confined to offshore workers and passing marine users.                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                                                | Underwater noise                                                                       | High            | Underwater noise is a key receptor due to the presence of marine mammals, sea turtles, fish, and other sensitive marine fauna within the wider Ionian Sea environment.                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                                                | Vibrations                                                                             | Low             | Drilling-related vibration effects are expected to remain localized to the immediate vicinity of the well and are not anticipated to affect wider environmental receptors.                                                                                                                                                                                                                                                                                                                                                                                                      |

| VALUED RECEPTOR (VR) |                           | VR SIGNIFICANCE | JUSTIFICATION                                                                                                                                                                           |
|----------------------|---------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | Electromagnetic radiation | Low             | The Project does not involve significant sources of electromagnetic emissions beyond standard offshore communications and operational equipment.                                        |
| Waters               | Seawater                  | High            | Seawater is a primary receptor due to the offshore nature of the Project and the potential for operational discharges, accidental releases, and interactions with marine water quality. |
|                      | Surface waters            | Low             | No direct interaction with inland surface waters is anticipated as no new onshore infrastructure or freshwater abstractions are required.                                               |
|                      | Groundwater               | Low             | The offshore location and absence of onshore construction activities mean that groundwater resources will not be directly affected.                                                     |

### 10.1.1.2 Environmental and social scoping

A preliminary scoping exercise has been undertaken for the routine activities associated with the Project in order to identify the environmental and social receptors that may potentially be affected and to focus the assessment on those interactions that are considered relevant. The scoping process provides the basis for defining the scope and level of detail of the Environmental and Social Impact Assessment (ESIA) and ensures that the assessment is proportionate to the nature, scale and characteristics of the proposed activities.

The methodology applied comprised the following steps:

- Identification of Project activities: identification and breakdown of the distinct activities associated with each phase of the Project (mobilisation and preparation, drilling operations, and demobilization / abandonment) that could potentially result in interactions with the physical, biological or socio-economic environment;
- Identification of environmental and social receptors: identification of the environmental and social receptors (or Significant Environmental Parameters, SEPs) present within the Project area and wider area of influence (Section 10.1.1.1);
- Screening of potential interactions: systematic review of the potential interaction pathways between Project activities and identified receptors, taking into account the nature, extent, duration and reversibility of the activity, as well as the sensitivity of the receptor;
- Preparation of an interaction matrix: development of a scoping matrix listing Project activities against the potentially affected receptors, to identify and record potential interactions and determine whether these should be carried forward for further assessment.

The interaction matrix (Table 10-2) was used as a screening tool to distinguish between interactions that are unlikely to result in measurable environmental or social effects and those that warrant further consideration. Interactions identified as having the potential to give rise to adverse or beneficial effects warranting further assessment (i.e. those scoped in) have been carried forward to the detailed impact assessment presented in the following sections. Interactions considered unlikely to result in significant effects, due to the nature of the activity, the characteristics of the receiving environment, or the implementation of embedded mitigation measures incorporated into the Project design or required by applicable regulatory and operational controls, have been scoped out from further detailed assessment.

Table 10-2: Project activities – Interaction with Environmental and Social Parameters

| Project Phase / Activity / Element                                                                                                              | Significant Environmental Parameters (SEPs) |                |                                               |           |                                               |                 |               |                      |          |                      |                   |                    |                  |                 |          |                           |                 |             |                              |                      |                          |                          |                   |                         |                                                                |                       |          |                 |                  |               |             |                |                  |            |                 |          |                |             |  |

### 10.1.1.3 Assessment of Environmental and Social Impacts

The final assessment of each potential impact results from the interaction between the nature of each impact (type, significance, and magnitude) and the importance of the respective Valued Receptor (Table 10-1). Consequently, the overall identification and evaluation of each potential impact depend on the intrinsic significance of the impact, the sensitivity, and the quality of the environment, as described in the following Sections.

#### 10.1.1.3.1 Calculation of the significance of impacts

The calculation of the significance of each impact is based on the Conesa method (Conesa, 2010), which was refined and adapted by the LDK study team so as, on the one hand, to align with international guidelines, the corresponding national and EU legislation, as well as internationally recognized best available practices, and on the other hand, to ensure the appropriate level of functionality in accordance with the technical parameters of the project under assessment and the environmental characteristics of the study area.

According to this method, the assessment of the significance of a project's or activity's impact on an environmental parameter results from evaluating the probability of occurrence of the project's/activity's effect, in conjunction with specific variables, including, among others, the intensity of the intervention, the extent, and the duration of the resulting effect.

The significance of impacts is assessed based on the qualitative outcome caused by each effect, which in turn is defined as the ratio by which the environmental impact is measured according to the degree of intensity of the generated change and the classification of the effect. This classification is based on qualitative criteria such as intensity (IN), extent (EX), moment of occurrence (MO), duration (PE), reversibility (RV), synergy (SI), accumulation (AC), type of effect (EF), periodicity (PR), and mitigation (MC).

Within the context of this Chapter, the probability of occurrence is not included among the qualitative criteria for determining the significance of the impact, as the activities and associated impact pathways assessed under routine operations are assumed to occur, where relevant, for the purposes of the assessment. Impacts with a lower probability of occurrence concern emergency events / accidents, which are assessed using a different methodology based on the probability of occurrence of the potential hazards and their consequences (see Chapter 9).

The qualitative evaluation criteria for calculating the significance of each impact are presented in the following Table.

**Table 10-3: Qualitative Assessment Criteria for the Environmental and Social Impacts of the Project**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <p><b>Nature:</b> Defines the nature of the impact, which may be Positive or Negative.</p> <p><b>Positive:</b> An impact considered to represent an improvement to the baseline or introduces a positive change.</p> <p><b>Negative:</b> An impact considered to represent a deterioration from the baseline or introduces an undesirable factor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <p><b>Intensity (IN):</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <p><b>Natural Environment (Biotic and Abiotic):</b> Intensity may be assessed in relation to the degree of change caused to the receptor (e.g. habitats, species or biocommunities, waters, soil, etc.). Receptor sensitivity and importance are considered separately in the final impact significance assessment. In detail:</p> <p><b>Negligible:</b> The impact on the environment is not detectable.</p> <p><b>Minor:</b></p> <ul style="list-style-type: none"> <li>The impact affects the environment in such a way that natural functions and processes are not significantly adversely affected (in case of a negative impact).</li> <li>The impact affects the environment in such a way that natural functions improve to a minor degree (in case of a positive impact).</li> </ul> <p><b>Moderate:</b></p> <ul style="list-style-type: none"> <li>When the affected receptor is altered, natural functions and processes continue, albeit in a modified form (in case of a negative impact).</li> <li>When the affected receptor is altered, yet natural functions and processes are significantly improved (in case of a positive impact).</li> </ul> <p><b>High:</b></p> <ul style="list-style-type: none"> <li>When natural functions or receptors are altered to such an extent that they may cease or become temporarily or permanently degraded (in case of a negative impact).</li> <li>When natural functions or receptors are significantly upgraded in relation to their existing condition (in case of a positive impact).</li> </ul> <p><b>Critical:</b></p> <ul style="list-style-type: none"> <li>When natural functions or receptors are altered to such an extent that they may cease or become irreversibly degraded (in case of a negative impact).</li> <li>When natural functions or receptors are substantially upgraded in relation to their existing condition (in case of a positive impact).</li> </ul> <p>Where relevant, national and/or international standards are used as a benchmark for assessing the impact. Specialised studies may contribute to quantifying the magnitude of impacts, where available and appropriate, with corresponding substantiated justification.</p> | <p><b>Anthropogenic &amp; Socio-economic Environment:</b></p> <p>The intensity may be assessed in terms of the ability of the individuals/communities affected by the Project to cope with or adapt to the negative changes caused by the Project (in the case of a negative impact), or the extent to which their quality of life/well-being will be enhanced as a result of the socio-economic benefits (in the case of a positive impact). Specifically:</p> <p><b>Negligible:</b> No perceptible change in the quality of life of the affected individuals/communities is recorded.</p> <p><b>Low:</b></p> <ul style="list-style-type: none"> <li>The affected individuals/communities can cope with/adapt to the negative impacts with relative ease and maintain their pre-impact quality of life/well-being (in the case of a negative impact).</li> <li>The affected individuals/communities will marginally benefit from the proposed activity and experience a relatively small improvement in their quality of life/well-being (in the case of a positive impact).</li> </ul> <p><b>Medium:</b></p> <ul style="list-style-type: none"> <li>The affected individuals/communities can cope with/adapt to the negative impacts with some difficulty and maintain their pre-impact livelihoods, but only with some degree of support to mitigate the impacts (in the case of a negative impact).</li> <li>The quality of life/well-being of the affected individuals/communities improves moderately as a result of the positive impacts.</li> </ul> <p><b>High:</b></p> <ul style="list-style-type: none"> <li>The affected individuals/communities can cope with/adapt to the negative impacts with significant difficulty and maintain their pre-impact livelihoods only with full support for impact mitigation (in the case of a negative impact).</li> <li>The quality of life/well-being of the affected individuals/communities improves significantly as a result of the positive impacts.</li> </ul> <p><b>Critical:</b></p> <ul style="list-style-type: none"> <li>The affected individuals/communities will not be able to cope with/adapt to the negative changes and will not be able to maintain their pre-impact quality of life/well-being (in the case of a negative impact).</li> <li>The quality of life/well-being of the individuals will improve remarkably because of the positive impacts.</li> </ul> |

#### Extent (EX):

The area of influence affected by the impact, including the project footprint and its immediate surrounding area. In detail:

- Within the Project Footprint:  
The impact is confined to a specific location within the boundaries of the project footprint.
- Local:  
The impact affects a limited geographical area surrounding the boundaries of the Project.
- Regional/National:  
The impact affects significant environmental resources at a regional or national level or is experienced on a regional/national scale (based on administrative boundaries, habitat/ecosystem type, etc.).
- International/Transboundary:  
The impact affects significant environmental resources at an international/transboundary level or is experienced on an international/transboundary scale.
- Critical:  
The impact (whether local or not) affects a critical area.

#### Moment of Occurrence (MO):

The time interval between the start of Project implementation and the manifestation of the impact on the environmental receptor under consideration.

- Immediate:  
The impact occurs simultaneously with the commencement of Project implementation (or within a very short time thereafter).
- Short-term:  
The impact occurs within one year from the start of Project implementation.
- Medium-term:  
The impact occurs between 2 and 10 years from the start of Project implementation.
- Long-term:  
The impact requires more than 10 years from the start of Project implementation to manifest.

#### Duration (PE):

The estimated duration of the impact, from the moment it manifests until the return to the pre-intervention condition, either through natural means or through the implementation of appropriate/targeted measures. In detail:

- Brief:  
The impact is expected to be of very short duration and intermittent/occasional. Its duration is practically negligible.
- Temporary:  
The impact lasts less than 1 year.
- Short-lived:  
The impact lasts from 1 to 10 years.
- Long-lived:  
The impact lasts from 11 to 25 years.
- Permanent:  
The impact lasts more than 25 years.

#### Reversibility (RV):

The ability of the receptor of the corresponding environmental parameter affected by the project/activity to recover through natural means and without human intervention. Impacts are characterised as reversible if the affected receptor can return to its original condition within a time period of less than 25 years.

In detail, reversibility may be:

- Short-term:  
When reversal occurs within 1 year.
- Medium-term:  
When reversal occurs within 2–10 years.
- Long-term:  
When reversal occurs within 11–15 years.

If the affected receptor cannot return to its pre-intervention condition without human intervention within a period of 15 years, the impact is considered irreversible by natural means.

#### Synergy (SI):

The phenomenon whereby the impact caused by an activity acts synergistically with the impacts of other activities—provided they are implemented simultaneously—leading to greater impacts (in terms of type, intensity, duration, extent, etc.) compared to the individual effect of each activity.

In detail, the impact may be:

- Non-synergistic:  
The impact of an activity is isolated, without any synergistic interaction.
- Synergistic:  
The impact of the activity may act synergistically with the impacts of other activities, if implemented simultaneously, resulting in greater impacts compared to the individual action of each activity.
- Highly synergistic:  
The impact of the activity may act synergistically with the impacts of other activities, if implemented simultaneously, resulting in significantly greater impacts compared to the individual action of each activity.

#### Accumulation (AC):

The progressive increase in the scale of the impact on the receptor of the corresponding environmental parameter when the impact persists over time.

In detail, the impact may be:

- Standalone (non-cumulative):  
The effect of the impact is isolated and does not cause additional cumulative impacts.
- Cumulative:  
The effect of the impact progressively increases due to the absence of means for elimination/minimisation when the activity causing the impact continues over an extended period. Additionally, cumulative impacts also arise from the aggregated effect of the activity on a receptor when it is added to other past, present, and future activities, regardless of the responsible party for those activities.

#### Effect (EF):

The cause-effect relationship, also known as the consequence of an activity.

In detail, the effect of an impact may be:

- Direct:  
The impact resulting from a direct interaction between a planned activity of the project and the receptor of a corresponding environmental parameter (e.g. between the occupation of an area and the pre-existing habitats, or between the discharge of effluents and the quality of the receiving water).
- Indirect:  
The impact resulting from other activities that are triggered as a secondary consequence of the Project (e.g. internal migration due to employment opportunities that generates demand for resources).

#### Periodicity (PR):

The manifestation of an impact or the repetition of a phenomenon either irregularly or according to a specific and defined pattern.

In detail, the impact may manifest as:

- Irregular and discontinuous:  
The impact occurs unpredictably and is repeated occasionally without following a specific or clear pattern.
- Continuous:  
The impact occurs in a steady and uninterrupted manner, which does not change significantly over time.
- Periodic:  
The impact occurs according to a specific and defined pattern, in a cyclical and recurring manner.

#### Restoration (MC):

The potential for full or partial restoration/recovery of the affected environmental parameter/receptor or process due

to the Project through the implementation of corrective measures, distinct from recovery through natural means assessed under Reversibility (RV).

In detail, the impact on the receptor may be:

- Restored immediately:  
The recovery/restoration of the receptor to its original condition is achieved through the implementation of corrective measures during the implementation of the proposed interventions or immediately upon their completion.
- Restored in the short-term:  
The recovery/restoration of the receptor to its original condition is achieved through the implementation of corrective measures within 1 year.
- Restored in the medium-term:  
The recovery/restoration of the receptor to its original condition is achieved through the implementation of corrective measures within 2–10 years.
- Restored in the Long-term:  
The recovery/restoration of the receptor to its original condition is achieved through the implementation of corrective measures within 11–15 years.
- Restored Partially:  
The impact is partially reversible through the implementation of corrective measures.
- Compensated/offset:  
The impact is irreversible through corrective measures but may be addressed through compensation/offsetting, where required by the applicable regulatory framework or expressly committed as Project mitigation.
- Cannot be restored:  
The impact is irreversible through the implementation of corrective measures, or the restoration period exceeds 15 years.

The significance of the impact is quantified by matching the corresponding numerical values to the evaluation criteria of the above Table, according to the Scoring Table (Table 10-4) provided below.

**Table 10-4: Scoring of Qualitative Assessment Criteria**

| QUALITATIVE IMPACT CRITERIA | QUALITATIVE ASSESSMENT CRITERIA | VALUE |
|-----------------------------|---------------------------------|-------|
| Nature (S)                  | Positive                        | +1    |
|                             | Negative                        | -1    |
| Intensity (IN)              | Negligible                      | 1     |
|                             | Minor                           | 2     |
|                             | Moderate                        | 4     |
|                             | High                            | 8     |
|                             | Critical                        | 12    |
| Extent (EX)                 | Within Project Site             | 1     |
|                             | Local                           | 2     |
|                             | Regional/National               | 4     |
|                             | International/Transboundary     | 8     |
|                             | Critical                        | +4*   |
| Time of Occurrence (MO)     | Long-term                       | 1     |
|                             | Medium-term                     | 2     |
|                             | Short-term                      | 3     |
|                             | Immediate                       | 4     |

| QUALITATIVE IMPACT CRITERIA                                                                                                 | QUALITATIVE ASSESSMENT CRITERIA  | VALUE |
|-----------------------------------------------------------------------------------------------------------------------------|----------------------------------|-------|
| Duration (PE)                                                                                                               | Brief                            | 1     |

| Periodicity (PR)                                                                                                            | Irregular and discontinuous      | 1     |
|                                                                                                                             | Periodic                         | 2     |
|                                                                                                                             | Continuous                       | 4     |
| Restoration (MC)                                                                                                            | Immediately restored             | 1     |
|                                                                                                                             | Short-term restoration           | 2     |
|                                                                                                                             | Medium-term restoration          | 3     |
|                                                                                                                             | Long-term restoration            | 4     |
|                                                                                                                             | Compensated / Partially restored | 4     |
|                                                                                                                             | Not restored                     | 8     |
| * For impacts occurring in critical areas, the value of 4 is added to the corresponding score for the extent of the impact. |                                  |       |

(Source: Conesa, 2010, as adapted by the LDK study team)

The following equation, which results from the weighting of the above criteria, is used to calculate the quantified value of the impact significance, **Im**:

$$Im = S * (3 * IN + 2 * EX + MO + PE + RV + SI + EF + PR + MC + AC)$$

Where, the **Im** prices range from **13** to the maximum value permitted by the scoring system.

As previously mentioned, in the present methodology the probability of occurrence is not included among the criteria for determining the significance of the impact, since the activities and associated impact pathways assessed under routine operations are assumed to occur, where relevant, for the purposes of the assessment. Therefore, the probability of occurrence is not included as a factor in the above equation. Lower-probability accidental and emergency events are assessed separately in Section **Error! Reference source not found..**

The quantified value of the significance of each impact is an absolute value (Im), which constitutes the **Magnitude of the Impact**.

### 10.1.1.3.2 Evaluation of Environmental and Social Impacts

As already stated, the Magnitude of the impact is the quantified value of the significance of each impact and, as such, indicates which of the potential impacts of the proposed project are relevant and potentially significant. However, since the absolute value of the magnitude of the impact (Im) can only be used for comparative consideration among the potential impacts, according to the Conesa method the correspondence of Im values has been standardized into categories, which are distinguished based on specific numerical thresholds and constitute clearly defined classes characterizing the significance of the impacts. The following presents the classification of impact significance, which are defined by the corresponding ranges of Im values, according to the Conesa method (as adapted by the LDK study team).

**Table 10-5: Significance characterization classes of each impact magnitude value (Im)**

| RANGE OF IM VALUES   | SIGNIFICANCE CHARACTERIZATION CLASSES OF EACH IMPACT |
|----------------------|------------------------------------------------------|
| $Im \leq 20$         | Negligible                                           |
| $21 \leq Im \leq 40$ | Low                                                  |
| $41 \leq Im \leq 60$ | Moderate                                             |
| $61 \leq Im \leq 85$ | High                                                 |
| $Im > 85$            | Very High                                            |

Source: Conesa, 2010, as adapted by the LDK study team

The classification of the significance of each impact is used in combination with the evaluation of the Valued Receptors (see Section 10.1.1), in order to determine the **Final Assessment** of each impact, which is characterized as **Negligible, Low, Moderate, Major or Critical** according to the Conesa method (Conesa, 2010), as adapted by the LDK study team (Table 10-6).

**Table 10-6: Final assessment of each environmental and social impact**

|                 |        | Impact Significance Classification |            |             |             |             |
|-----------------|--------|------------------------------------|------------|-------------|-------------|-------------|
|                 |        | Negligible                         | Low        | Moderate    | High        | Very high   |
| VR Significance | Low    | Negligible                         | Negligible | Minor       | Moderate    | Significant |
|                 | Medium | Negligible                         | Minor      | Moderate    | Significant | Critical    |
|                 | High   | Minor                              | Moderate   | Significant | Critical    | Critical    |

The above impact significance categories correspond to the definitions presented in the following Table.

**Table 10-7: Definition of the Significance of Environmental and Social Impacts**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Critical</b>    | Impacts above an acceptable threshold, resulting in permanent loss of environmental quality without the possibility of restoration, regardless of the application of preventive or corrective measures. These impacts are non-reversible.<br><br>Therefore, it is a potentially unacceptable impact, as it corresponds to a severe effect that cannot be adequately mitigated. Alternative locations or designs would need to be considered, or other measures identified to avoid or reduce the impact to an acceptable level, subject to the applicable regulatory decision-making process. |
| <b>Significant</b> | Impacts that require extensive and intensive preventive or corrective measures for the receptor to return to its original state. Even with such measures, the restoration period is medium- to long-term.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Moderate</b>    | Impacts that do not require extensive and intensive measures for the receptor to return to its original state, or the degree of disturbance is not great, possibly short-term, and recovery is short- to medium-term. In some cases, these impacts are subject to mitigation and require specific corrective actions where applicable, without extensive efforts.                                                                                                                                                                                                                             |
| <b>Minor</b>       | Impacts that cause detectable but not significant changes to the condition of the receptors. They may require mild or no mitigation measures. In some cases, even without the implementation of corrective actions, such minor impacts are of short duration and tend to subside naturally or through simple and limited measures.                                                                                                                                                                                                                                                            |
| <b>Negligible</b>  | Impacts that can be reversed naturally or immediately cease when the activity ends and do not require preventive or corrective measures. Negligible impacts are considered reversible, short-term, and without the need for corrective intervention.                                                                                                                                                                                                                                                                                                                                          |
| <b>Positive</b>    | Impacts that result in an <u>improvement</u> in the quality/condition of the receptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 10.1.2 Impacts related to climate resilience

### 10.1.2.1 Impacts on climatic and bioclimatic characteristics

No significant adverse impacts on the climatic and bioclimatic characteristics of the study area are expected as a result of the Project during any phase of its implementation. The proposed Asopus-1 exploration drilling campaign is temporary in nature, of limited duration, and does not involve permanent offshore or onshore infrastructure that could alter local climatic, microclimatic, or bioclimatic conditions.

#### 10.1.2.1.1 Drilling preparation and mobilization phase

Due to the nature and scale of the implementation works, the drilling preparation and mobilization phase of the Project is not expected to cause any change in the climatic and bioclimatic characteristics of the study area. Mobilisation activities, including the preparation and operation of the logistics base, loading and unloading activities at the port, helicopter transfers, and transit of the MODU and support vessels to the well location, are temporary and of short duration. These activities will not result in any measurable changes to local or regional climatic conditions, such as temperature, precipitation, humidity, or wind patterns.

Minor greenhouse gas (GHG) emissions will be generated through fuel combustion from vessels, helicopters, cargo handling equipment, and road transport; however, these emissions will be short-term and negligible in terms of their influence on the climatic and bioclimatic characteristics of the area.

In summary, with regard to their significance, the impacts expected on climatic and bioclimatic characteristics during the mobilisation phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=2), immediate (MO=4), coincident with mobilisation activities (PE=1), short-term reversible (RV=1), synergistic (SI=2), indirect (EF=1), discontinuous (PR=1), of short-term recovery (MC=2), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on Climatic and Bioclimatic Characteristics  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

|                                                      |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |
| Mobilisation of MODU to well site – power generation | -          | 1              | 2           | 4           | 1                | 1                  | 2            | 1           | 1                | 2             | 1                 | 20                    | Negligible | Medium                     | NEGLIGIBLE          |

#### 10.1.2.1.2 Exploration drilling operations phase

During the drilling operations phase, no direct adverse effects on local climate, microclimate, or bioclimatic conditions are anticipated. The offshore drilling campaign will be undertaken using a dynamically positioned MODU and associated support vessels over a limited period and will not involve permanent structures or activities capable of altering climatic processes.

The principal interaction with climatic receptors during this phase relates to the generation of atmospheric emissions, including GHG emissions, resulting from the continuous operation of the MODU, support vessels, power generation systems, and helicopter logistics. Although these emissions contribute incrementally to global climate change, the contribution of the Project is expected to be minor in the context of regional and global emissions inventories due to the temporary and exploratory nature of the activity.

Climatic and meteorological conditions, including wind, wave conditions, and extreme weather events, will also influence operational safety and planning, and will therefore be continuously monitored throughout drilling operations.

In summary, with regard to their significance, the impacts expected on climatic and bioclimatic characteristics during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN=1-2), widespread but limited to the offshore operational area (EX=2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term reversible following cessation of activities (RV=1), synergistic (SI=2), indirect (EF=1), continuous during operations (PR=4) or occasional (PR=1), of short-term recovery after completion of drilling (MC=2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

| Impacts on Climatic and Bioclimatic Characteristics |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |
|-----------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|-----|----------------------------|---------------------|
| Project Activities / Elements                       | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |     | Valued Receptor Assessment | Impact Significance |

| Impacts on Climatic and Bioclimatic Characteristics     |   |   |   |   |   |   |   |   |   |   |   |    |            |        |            |
|---------------------------------------------------------|---|---|---|---|---|---|---|---|---|---|---|----|------------|--------|------------|
| Operation of onshore facilities, equipment and vehicles | - | 1 | 2 | 4 | 1 | 1 | 2 | 1 | 4 | 2 | 1 | 23 | Low        | Medium | MINOR      |
| Helicopter transfers between heliport and MODU          | - | 1 | 2 | 4 | 1 | 1 | 2 | 1 | 1 | 2 | 1 | 20 | Negligible | Medium | NEGLIGIBLE |

### 10.1.2.1.3 Demobilisation and abandonment phase

No significant adverse impacts on climatic and bioclimatic characteristics are expected during the abandonment and demobilisation phase. Activities associated with well plugging and abandonment, recovery of subsea equipment, demobilisation of the MODU, and removal of temporary onshore facilities are of limited duration and will not alter local or regional climatic conditions.

Similar to the mobilisation phase, temporary GHG emissions will be generated through vessel operations, equipment use, and transport activities associated with demobilisation; however, these emissions will be short-term and minor. Consequently, the abandonment and demobilisation phase is not expected to result in any measurable effects on the climatic or bioclimatic characteristics of the study area.

In summary, with regard to their significance, the impacts expected on climatic and bioclimatic characteristics during the demobilisation and abandonment phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=2), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), synergistic (SI=2), indirect (EF=1), discontinuous (PR=1), of short-term recovery (MC=2), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on Climatic and Bioclimatic Characteristics |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

| MODU circulation and surface handling operations    | -          | 1              | 2           | 4           | 1                | 1                  | 2            | 1           | 1                | 2             | 1                 | 20                    | Negligible | Medium                     | NEGLIGIBLE          |

### 10.1.2.2 Climate change mitigation

The carbon footprint of the Asopus-1 exploration drilling campaign was quantified in accordance with ISO 14064-1:2018, considering direct greenhouse gas (GHG) emissions arising from offshore and onshore supporting activities. Emissions were classified according to the GHG Protocol into Scope 1 (direct fuel combustion), Scope 2 (electricity for onshore logistics facilities) and Scope 3 (other indirect emissions associated with supply chain activities, waste management and contractor services).

The Project comprises a temporary offshore exploration drilling campaign of limited duration and does not include hydrocarbon production, routine flaring, long-term operation of fixed installations or permanent

infrastructure. Consequently, the Project's carbon footprint is almost entirely associated with fuel combustion by the Mobile Offshore Drilling Unit (MODU), support vessels, helicopter operations and onshore logistics support activities.

Based on the activity data of the Project, the emission factors derived from the annual publication of the Ministry of Environment and Energy for implementation of the National Climate Law and the 2006 IPCC Guidelines, the total direct greenhouse gas emissions (Scope 1) of the drilling campaign are estimated at 15,596.56 tCO<sub>2</sub>eq. Of this total, approximately 15,534.36 tCO<sub>2</sub>eq originate from offshore operations, while only 62.20 tCO<sub>2</sub>eq arise from onshore support activities. The offshore drilling unit (MODU) constitutes the dominant emission source, accounting for approximately 61% of total emissions, followed by offshore support vessels (approximately 36%), whereas helicopter and onshore activities contribute only marginally.

The calculated carbon emissions are temporary, associated exclusively with the exploration drilling campaign. No routine hydrocarbon production, processing, storage or export activities are included within the Project scope. Furthermore, no well testing involving hydrocarbon flow, routine venting or routine flaring is currently planned. Accordingly, dedicated methane leak detection and repair (LDAR) obligations under Regulation (EU) 2024/1787 on methane emissions in the energy sector are not expected to be triggered. Nevertheless, contractor management systems and incident reporting procedures will be implemented to ensure that any accidental methane releases are identified, recorded and reported in accordance with applicable legislation.

The carbon footprint assessment was undertaken in the context of the national and European climate policy framework, including the European Climate Law, the European Green Deal, the National Climate Law (Law 4936/2022) and the revised National Energy and Climate Plan (NECP, GG 6983/B/19.12.2024). According to the revised NECP, total national greenhouse gas emissions in Greece were approximately 76.9 Mt CO<sub>2</sub>eq in 2022, while national emissions are projected to decrease substantially by 2030 and towards climate neutrality by 2050.

Within this context, the total carbon footprint of the Asopus-1 drilling campaign corresponds to approximately 0.020% of Greece's total greenhouse gas emissions in 2022. The Project will be temporary, will not involve hydrocarbon production, and offshore operations will be limited to the exploration drilling campaign. As a result, it is not expected to materially affect Greece's progress towards the national and European climate targets for 2030 and 2050.

In addition, the MODU operator, Stena Drilling, operates an Energy Management System certified in accordance with ISO 50001:2018, while the MODU carries the voluntary DNV Abate (P) notation, which promotes efficient power generation, fuel optimisation and continuous improvement in greenhouse gas management performance. These measures are considered consistent with recognised international good industry practice for reducing energy consumption and associated emissions.

Although greenhouse gas emissions will occur during drilling operations, these emissions are unavoidable for offshore exploration activities and are inherently limited by the short duration of the drilling campaign. The Project does not create a long-term source of greenhouse gas emissions and does not compromise the achievement of national or EU climate objectives. Consequently, the contribution of the Project to climate change is considered negative, of low magnitude, temporary, reversible and not significant at national or regional scale.

In conclusion, as summarised in Table 10-8 (in accordance with the table provided in Annex 8 of Ministerial Decision ΥΠΕΝ/ΔΙΠΑ/143898/9866, GG 7322/Β/31.12.2024), the carbon footprint of the Project, which is associated exclusively with the temporary exploration drilling campaign and its supporting activities, is considered proportionately negligible at the national scale. Considering the absence of permanent installations, the lack of hydrocarbon production activities and the time-limited duration of the drilling campaign, the Project is not expected to hinder the achievement of national or European greenhouse gas emission reduction targets or the objective of climate neutrality by 2050. Therefore, the Project is considered fully compatible with the objectives of the revised National Energy and Climate Plan (NECP), the European Green Deal and the broader European climate policy framework.

**Table 10-8: Project Impacts in Relation to Climate Change Mitigation Issues (Annex 8 of MD 143898/9866/2024)**

| CLIMATE CHANGE MITIGATION ISSUE                                                                                                                                                | PROJECT IMPACTS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alignment with the Paris Agreement and the "Do No Significant Harm" principle                                                                                                  | The Project consists of a temporary offshore exploration drilling campaign without hydrocarbon production, routine venting or flaring. The total direct carbon footprint is estimated at 15,596.56 tCO <sub>2</sub> eq, representing approximately 0.020% of Greece's total GHG emissions in 2022. The Project is therefore considered compatible with the objectives of the Paris Agreement, the European Climate Law and the National Energy and Climate Plan and does not compromise the achievement of climate neutrality objectives. |
| Direct greenhouse gas emissions                                                                                                                                                | Direct emissions arise primarily from fuel combustion by the MODU, support vessels and helicopter. Total Scope 1 emissions are estimated at 15,596.56 tCO <sub>2</sub> eq. Emissions are temporary, limited to the drilling campaign duration and managed through application of recognised industry standards and energy efficiency measures.                                                                                                                                                                                            |
| Indirect greenhouse gas emissions due to an increased demand for energy                                                                                                        | Limited indirect emissions (Scope 2) may arise from electricity consumption associated with logistics base activities. These emissions are expected to be minor compared with offshore fuel combustion and will progressively decrease as the national electricity mix decarbonises in accordance with the revised NECP.                                                                                                                                                                                                                  |
| Indirect greenhouse gas emissions caused by any supporting activities or infrastructure that is directly linked to the implementation of the proposed project (e.g. transport) | Additional indirect emissions may arise from supply chain activities, contractor transport, waste management and logistics support (Scope 3). These emissions are temporary and associated with the short-term implementation of the drilling campaign.                                                                                                                                                                                                                                                                                   |

### 10.1.2.3 Climate change adaptation

The resilience and adaptive capacity of the Project to climate change are assessed and evaluated. The assessment is based on the analysis of climate vulnerability (i.e. the sensitivity and exposure of the Project to climate-related hazards), climate risk analysis (i.e. the likelihood of occurrence and potential consequences of climate-related hazards), and the review of the compatibility of the Project with existing climate change adaptation strategies and plans.

The screening stage includes an assessment of the Project's vulnerability to climate change. The vulnerability assessment is undertaken through three sequential steps comprising the following methodological elements:

- Analysis of Project sensitivity to climate-related hazards;

- Analysis of current and future exposure of the Project to climate hazards under relevant climate scenarios;
- Integration of sensitivity and exposure analyses in order to determine the overall climate vulnerability of the Project.

The outcome of the vulnerability assessment forms the basis for the subsequent climate risk assessment and for the identification, where necessary, of adaptation and resilience measures to ensure the safe and sustainable implementation of the Project under both current and future climatic conditions.

The National Coordination Authority of the Ministry of Development and Investments, in cooperation with the JASPERS (Joint Assistance to Support Projects in European Regions) initiative and with the support of the Ministry of Environment and Energy and the Ministry of Infrastructure and Transport, developed a methodology for assessing the climate resilience of infrastructure projects with an expected operational lifetime of at least five (5) years, in accordance with Article 73(2)(j) of Regulation (EU) 2021/1060.

The Project comprises a short-duration offshore exploration drilling campaign and therefore falls outside the formal scope of the methodology. Nonetheless, the assessment adopts the underlying principles of sensitivity, exposure and vulnerability analysis, proportionately adapted to the temporary nature and operational characteristics of the Asopus-1 exploration well, in order to evaluate its resilience to climate-related hazards and consistency with applicable climate adaptation policies.

### 10.1.2.3.1 Screening

#### 10.1.2.3.1.1 Sensitivity analysis

The purpose of the sensitivity analysis is to identify the climate hazards relevant to the specific type of Project, based on its design, mobilisation and operational characteristics, irrespective of its geographical location. Sensitivity of a project therefore relates primarily to its intrinsic characteristics.

Important inputs to the sensitivity analysis include the technical and design characteristics of the Project, as defined in the relevant engineering and design studies. A climate hazard is understood as the potential occurrence of a natural physical event or trend that may cause loss of life, injury, or other adverse health impacts, as well as damage to or loss of property, infrastructure, livelihoods, services, ecosystems and environmental resources.

A comprehensive inventory of climate hazards is provided in the EU Taxonomy Climate Delegated Act<sup>60</sup> and in the European Commission Technical Guidance on Climate Proofing of Infrastructure (2021/C 373/01). These documents distinguish between chronic climate hazards and acute (extreme weather) hazards and classify them into broad categories, including:

- Temperature-related hazards (e.g. heat stress, wildfires);
- Wind-related hazards (e.g. storms, cyclones);

---

<sup>60</sup> Commission Delegated Regulation (EU) 2021/2139 of 4 June 2021 supplementing Regulation (EU) 2020/852 of the European Parliament and of the Council by establishing the technical screening criteria for determining the conditions under which an economic activity qualifies as contributing substantially to climate change mitigation or climate change adaptation and for determining whether that economic activity causes no significant harm to any of the other environmental objectives.

- Water-related hazards (e.g. sea level rise, drought, flooding);
- Solid mass-related hazards (e.g. coastal erosion, landslides).

Additional climate hazard inventories are provided in JASPERS guidance documents, many of which overlap with the European Commission classifications. Certain hazards included in international inventories may not be relevant in the Greek context due to geographical and climatic conditions (for example, hazards associated with permafrost thawing). Furthermore, climate hazards identified in the applicable Regional Climate Change Adaptation Plans have also been considered.

For the purposes of the present ESIA, a consolidated climate hazard inventory has been developed by combining the above sources. The sensitivity assessment for the Project, following the methodology and screening approach adopted by the General Secretariat for Public Investments and the National Strategic Reference Framework (NSRF) (<https://adaptivegreecehub.gr/eleghos-klimatikis-anthektikotitas>), is summarised in Table 10-9.

Sensitivity categories are defined qualitatively as Low, Medium or High, taking into account the Project's mobilisation, drilling and abandonment/decommissioning characteristics, associated activities and services, and its integration within the surrounding environment. The overall sensitivity rating reflects the combined influence of these factors in accordance with the climate resilience assessment methodology adopted for the Project.

**Table 10-9: Sensitivity Analysis**

| CLIMATE-RELATED HAZARDS                                      | SENSITIVITY ANALYSIS       |          |                       |                             |                     |
|--------------------------------------------------------------|----------------------------|----------|-----------------------|-----------------------------|---------------------|
|                                                              | MOBILISATION / PREPARATION | DRILLING | ACTIVITIES / SERVICES | INTEGRATION WITHIN THE AREA | OVERALL SENSITIVITY |
| Heatwave                                                     | Low                        | Low      | Low                   | Low                         | Low                 |
| Cold wave                                                    | Low                        | Low      | Low                   | Low                         | Low                 |
| Frost (number of days with Tmin < 0°C)                       | Low                        | Low      | Low                   | Low                         | Low                 |
| Wildfire                                                     | Low                        | Low      | Medium                | Low                         | Medium              |
| Cyclones, severe storms, hurricanes                          | High                       | High     | High                  | Medium                      | High                |
| Storms (including snowstorms and dust storms)                | Medium                     | Medium   | Medium                | Medium                      | Medium              |
| Tornadoes / Extreme winds                                    | High                       | High     | High                  | High                        | High                |
| Drought                                                      | Low                        | Low      | Low                   | Low                         | Low                 |
| Heavy precipitation (rain, hail, snow/ice)                   | Low                        | Low      | Medium                | Medium                      | Medium              |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | Medium                     | Medium   | Medium                | Medium                      | Medium              |
| Landslides / Soil erosion                                    | Low                        | Low      | Low                   | Low                         | Low                 |
| Land subsidence                                              | Low                        | Low      | Low                   | Low                         | Low                 |
| Changes in average air temperature                           | Low                        | Low      | Low                   | Low                         | Low                 |
| Urban heat island effect                                     | Low                        | Low      | Low                   | Low                         | Low                 |
| Heat stress                                                  | Low                        | Low      | Low                   | Low                         | Low                 |
| Temperature variability                                      | Low                        | Low      | Low                   | Low                         | Low                 |

| CLIMATE-RELATED HAZARDS                                                      | SENSITIVITY ANALYSIS       |          |                       |                             |                     |
|------------------------------------------------------------------------------|----------------------------|----------|-----------------------|-----------------------------|---------------------|
|                                                                              | MOBILISATION / PREPARATION | DRILLING | ACTIVITIES / SERVICES | INTEGRATION WITHIN THE AREA | OVERALL SENSITIVITY |
| Changes in solar radiation                                                   | Low                        | Low      | Low                   | Low                         | Low                 |
| Changes in wind characteristics                                              | Medium                     | High     | High                  | Medium                      | High                |
| Changes in precipitation characteristics and patterns (rain, hail, snow/ice) | Low                        | Low      | Low                   | Low                         | Low                 |
| Precipitation variability or hydrological variability                        | Low                        | Low      | Low                   | Low                         | Low                 |
| Changes in mean water temperature of water bodies                            | Low                        | Medium   | Low                   | Medium                      | Medium              |
| Ocean acidification / changes in seawater salinity                           | Low                        | Medium   | Low                   | Medium                      | Medium              |
| Saltwater intrusion and salinisation of surface and groundwater              | Low                        | Low      | Low                   | Low                         | Low                 |
| Sea level rise                                                               | Medium                     | Medium   | Medium                | Medium                      | Medium              |
| Water availability and water resource stress                                 | Low                        | Low      | Low                   | Low                         | Low                 |
| Coastal erosion                                                              | Low                        | Medium   | Medium                | Medium                      | Medium              |
| Soil degradation, salinisation and desertification                           | Low                        | Low      | Low                   | Low                         | Low                 |
| Changes in the length of farming seasons                                     | Low                        | Low      | Low                   | Low                         | Low                 |

#### 10.1.2.3.1.2 Exposure analysis

The purpose of the exposure analysis is to identify the climate hazards relevant to the geographical location of the Project, both under current and future climatic conditions, irrespective of the type of Project activity. Exposure therefore relates to the extent to which the Project is likely to be exposed to climate-related hazards as a result of its location and the prevailing and projected climatic conditions in the study area.

For the exposure analysis, the same climate hazard inventory adopted for the sensitivity assessment has been used. The assessment considers both present-day climate conditions and projected future climate scenarios, taking into account the available climatic information presented in Chapter 8 of this ESIA, together with regional climate projections and relevant climate adaptation planning documents.

For the purposes of this assessment, future climate conditions have been considered over a timeframe relevant to the temporary duration of the offshore exploration drilling campaign, while also taking into account longer-term (near future, 2031 – 2060) climate trends that may influence the operational environment within the wider offshore area.

More specifically, the exposure analysis for the Project, based on the information presented in Chapter 8 and following the methodology and screening approach developed by the General Secretariat for Public Investments and NSRF (<https://geo.adaptivegreecehub.gr>), is summarised in Table 10-10, using relevant indices for the intermediate (RCP 4.5) and extreme (RCP 8.5) scenarios.

**Table 10-10: Exposure Assessment for Climate Hazards**

| CLIMATE-RELATED HAZARDS                                      | RELEVANT INDEX                                                                                                                                                                                            | RCP 4.5       | RCP 8.5       | COMMENTS / GEOGRAPHICAL LOCATION |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|----------------------------------|
| Heatwave                                                     | Number of days with TX > 35 °C - very hot days                                                                                                                                                            | 12 – 13       | 14 – 15       | Port of Igoumenitsa              |
| Frost                                                        | Number of days with Tmin < 0 °C                                                                                                                                                                           | 17 – 19       | 16 – 18       | Port of Igoumenitsa              |
| Wildfire                                                     | Mean Forest Fire Weather Index (FWI) during the fire season (May–October)                                                                                                                                 | 31.6 – 31.8   | 31.8 – 32.0   | Port of Igoumenitsa              |
| Tornadoes / Extreme winds                                    | Mean wind velocity (m/s)                                                                                                                                                                                  | 4.0 – 4.7     | 4.0 – 4.7     | West shores of Corfu             |
|                                                              |                                                                                                                                                                                                           | 3.3 – 3.4     | 3.2 – 3.3     | Port of Igoumenitsa              |
| Drought                                                      | Maximum number of consecutive days with PR < 1mm – maximum dry spell duration (in days)                                                                                                                   | 56 – 57       | 54 – 55       | Port of Igoumenitsa              |
| Heavy precipitation (rain, hail, snow/ice)                   | Number of days with PR > 10mm - days with heavy rainfall                                                                                                                                                  | 45 – 47       | 44 – 46       | Port of Igoumenitsa              |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | The Port of Igoumenitsa is located within an Area of Potential Significant Flood Risk (APSFR) ELO5APSFR008 (Kalamas river down coarse-delta and coastal area of Igoumenitsa) (Figure 10-1).               |               |               |                                  |
| Landslides / Soil erosion                                    | The Port of Igoumenitsa is not located on sloping ground                                                                                                                                                  |               |               |                                  |
| Urban heat island effect                                     | The Port of Igoumenitsa is not located within a densely built urban area and is therefore considered to have low exposure to urban heat island effects and thermal hotspots.                              |               |               |                                  |
| Heat stress                                                  |                                                                                                                                                                                                           |               |               |                                  |
| Temperature variability                                      | Mean minimum temperature (°C) – TN                                                                                                                                                                        | 12.1 – 12.3   | 12.5 – 12.7   | Port of Igoumenitsa              |
|                                                              | Mean maximum temperature (°C) – TX                                                                                                                                                                        | 20.9 – 21.0   | 21.2 – 21.3   |                                  |
| Changes in solar radiation                                   | Mean annual received short wave radiation (Watt/m <sup>2</sup> )                                                                                                                                          | 188.0 – 188.3 | 188.2 – 188.5 | Port of Igoumenitsa              |
| Sea level rise                                               | The Port of Igoumenitsa is located within the coastal zone, as defined in Law 4546/2018 (GG 101/A/2018). However, it is not within an area that will be flooded by potential sea level rise (Figure 10-2) |               |               |                                  |
| Water availability and water resource stress                 | The Asopus-1 Project does not require significant freshwater resources (>1,000,000 m <sup>3</sup> /year); therefore, its sensitivity to water availability and water stress is considered Low.            |               |               |                                  |

With regard specifically to flood risk, the Project's exposure is High, as the shore base is partly within the Area of Potential Significant Flood Risk (APSFR) ELO5APSFR008 (Kalamas river down coarse-delta and coastal area of Igoumenitsa), and within modelled inundation areas associated with fluvial flooding scenarios corresponding to return periods of T=50 years, T=100 years, and T=1000 years (Figure 10-1).

**Figure 10-1: APSFR EL05APSFR008 in the area of Igoumenitsa Port**

Regarding the risk source of sea level rise, the exposure of the Project was assessed as low, as the area of the examined site is located in regions not identified by the referenced mapping as subject to inundation under the assessed sea-level-rise scenario of up to 1 metre.

Source: Flood Risk Maps, <https://gis.floods.vpeka.gr>

Figure 10-2: Depth due to sea level rise for a return period of T=100 years

The overall exposure to climate related hazards is qualitatively classified as Low, Medium or High for both current conditions and future climate conditions. The overall exposure rating is subsequently derived from the combination of these two assessments and provides the basis for the subsequent climate vulnerability assessment of the Project.

Table 10-11: Exposure Analysis

| CLIMATE-RELATED HAZARDS                                      | EXPOSURE ANALYSIS  |                   |                |
|--------------------------------------------------------------|--------------------|-------------------|----------------|
|                                                              | CURRENT CONDITIONS | FUTURE CONDITIONS | TOTAL EXPOSURE |
| Heatwave                                                     | Low                | Low               | Low            |
| Cold wave                                                    | Low                | Low               | Low            |
| Frost (number of days with Tmin < 0 °C)                      | Low                | Low               | Low            |
| Wildfire                                                     | Low                | Low               | Low            |
| Cyclones, severe storms, hurricanes                          | Low                | Low               | Low            |
| Storms (including snowstorms and dust storms)                | Low                | Low               | Low            |
| Tornadoes / Extreme winds                                    | Low                | Low               | Low            |
| Drought                                                      | Low                | Low               | Low            |
| Heavy precipitation (rain, hail, snow/ice)                   | Low                | Low               | Low            |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | Medium             | High              | High           |
| Landslides / Soil erosion                                    | Low                | Low               | Low            |

| CLIMATE-RELATED HAZARDS                                                      | EXPOSURE ANALYSIS  |                   |                |
|------------------------------------------------------------------------------|--------------------|-------------------|----------------|
|                                                                              | CURRENT CONDITIONS | FUTURE CONDITIONS | TOTAL EXPOSURE |
| Land subsidence                                                              | Low                | Low               | Low            |
| Changes in average air temperature                                           | Low                | Low               | Low            |
| Urban heat island effect                                                     | Low                | Low               | Low            |
| Heat stress                                                                  | Low                | Low               | Low            |
| Temperature variability                                                      | Low                | Low               | Low            |
| Changes in solar radiation                                                   | Low                | Low               | Low            |
| Changes in wind characteristics                                              | Medium             | Medium            | Medium         |
| Changes in precipitation characteristics and patterns (rain, hail, snow/ice) | Low                | Low               | Low            |
| Precipitation variability or hydrological variability                        | Low                | Low               | Low            |
| Changes in mean water temperature of water bodies                            | Low                | Low               | Low            |
| Ocean acidification / changes in seawater salinity                           | Low                | Low               | Low            |
| Saltwater intrusion and salinisation of surface and groundwater              | Low                | Low               | Low            |
| Sea level rise                                                               | Low                | Medium            | Medium         |
| Water availability and water resource stress                                 | Low                | Low               | Low            |
| Coastal erosion                                                              | Low                | Low               | Low            |
| Soil degradation, salinisation and desertification                           | Low                | Low               | Low            |
| Changes in the length of farming seasons                                     | Low                | Low               | Low            |

#### 10.1.2.3.1.3 Vulnerability Analysis

The vulnerability analysis combines the results of the exposure and sensitivity assessments, to identify which climate-related hazards are relevant to the Project, considering both the nature of the Project and its geographical location. It provides the basis for determining whether the assessment should proceed to the second stage of a detailed climate risk analysis.

For the purposes of sensitivity and exposure assessments, a three-level rating scale (Low, Medium, High) has been adopted to indicate the degree of vulnerability associated with each climate-related hazard.

Where a given hazard is relevant to both the sensitivity and exposure of the Project, the resulting vulnerability of the Project to that hazard is determined through the combination of the two assessments. The overall vulnerability rating therefore reflects both the intrinsic susceptibility of the Project to a specific climate hazard and the extent to which the Project is exposed to that hazard under present and future climatic conditions.

$$\text{VULNERABILITY} = \text{COMBINATION} \{ \text{SENSITIVITY}, \text{EXPOSURE} \}$$

If the vulnerability analysis demonstrates, with appropriate justification, that the Project is not vulnerable to any climate-related hazard, no further climate risk analysis is required, and the climate adaptation assessment may be considered complete.

However, where medium or high levels of vulnerability are identified for specific hazards, a detailed climate risk assessment should be undertaken for each of these hazards.

More specifically, the vulnerability assessment for the Project, undertaken in accordance with the assessment tool developed by the General Secretariat for Public Investments and NSRF, is summarised in the following Table.

**Table 10-12: Vulnerability Assessment for the Project**

| CLIMATE-RELATED HAZARDS                                                      | SENSITIVITY | EXPOSURE | VULNERABILITY |
|------------------------------------------------------------------------------|-------------|----------|---------------|
| Heatwave                                                                     | Low         | Low      | Low           |
| Cold wave                                                                    | Low         | Low      | Low           |
| Frost (number of days with Tmin < 0°C)                                       | Low         | Low      | Low           |
| Wildfire                                                                     | Medium      | Low      | Low           |
| Cyclones, severe storms, hurricanes                                          | High        | Low      | Medium        |
| Storms (including snowstorms and dust storms)                                | Medium      | Low      | Low           |
| Tornadoes / Extreme winds                                                    | High        | Low      | Medium        |
| Drought                                                                      | Low         | Low      | Low           |
| Heavy precipitation (rain, hail, snow/ice)                                   | Medium      | Low      | Low           |
| Flooding (coastal, fluvial, pluvial or groundwater flooding)                 | Medium      | High     | High          |
| Landslides / Soil erosion                                                    | Low         | Low      | Low           |
| Land subsidence                                                              | Low         | Low      | Low           |
| Changes in average air temperature                                           | Low         | Low      | Low           |
| Urban heat island effect                                                     | Low         | Low      | Low           |
| Heat stress                                                                  | Low         | Low      | Low           |
| Temperature variability                                                      | Low         | Low      | Low           |
| Changes in solar radiation                                                   | Low         | Low      | Low           |
| Changes in wind characteristics                                              | High        | Medium   | High          |
| Changes in precipitation characteristics and patterns (rain, hail, snow/ice) | Low         | Low      | Low           |
| Precipitation variability or hydrological variability                        | Low         | Low      | Low           |
| Changes in mean water temperature of water bodies                            | Medium      | Low      | Low           |
| Ocean acidification / changes in seawater salinity                           | Medium      | Low      | Low           |

| CLIMATE-RELATED HAZARDS                                         | SENSITIVITY | EXPOSURE | VULNERABILITY |
|-----------------------------------------------------------------|-------------|----------|---------------|
| Saltwater intrusion and salinisation of surface and groundwater | Low         | Low      | Low           |
| Sea level rise                                                  | Medium      | Medium   | Medium        |
| Water availability and water resource stress                    | Low         | Low      | Low           |
| Coastal erosion                                                 | Medium      | Low      | Low           |
| Soil degradation, salinisation and desertification              | Low         | Low      | Low           |
| Changes in the length of farming seasons                        | Low         | Low      | Low           |

The above analysis indicates that medium or high levels of vulnerability may arise for certain climate-related hazards. Consequently, where such vulnerability levels have been identified, a detailed climate risk assessment has been undertaken for each relevant hazard, as presented in the following Section.

#### 10.1.2.3.2 Risk assessment

The risk assessment is undertaken for those climate hazards identified through the vulnerability assessment as presenting medium or high levels of vulnerability. Risk assessment represents the combination of the likelihood of occurrence of each climate hazard identified during the vulnerability screening stage and the magnitude of the potential consequences associated with that hazard.

Various approaches may be used to describe the likelihood of occurrence of climate hazards. However, it is important to initially define the scale that will be applied and clearly explain how the likelihood of occurrence is evaluated and what each likelihood category represents. The selected scale should be appropriate to the characteristics of the Project and should be applied consistently throughout the assessment. In accordance with the European Commission Technical Guidance on the Climate Proofing of Infrastructure (2021/C 373/01), the likelihood of occurrence of a specific hazard may be described using either qualitative or quantitative criteria.

Each likelihood category should be accompanied by a clear description. For example, where qualitative descriptors such as unlikely, possible or likely are used, the meaning of each category in the context of the specific climate hazard and Project should be explicitly defined.

With regard to the assessment of consequences, the Technical Guidance emphasises that consideration should be given not only to direct impacts, but also to potential secondary, indirect and cumulative effects. The assessment should therefore consider the adaptive capacity of the wider system within which the infrastructure operates. Adaptive capacity refers to the ability of systems, institutions, humans and other organisms to adjust to potential damage, take advantage of opportunities, or respond to the consequences of climate change.

For the purposes of the present ESIA, risk assessment has been undertaken by combining the likelihood of occurrence of each relevant climate hazard with the severity of its potential consequences for the Project. The assessment considers both current and future climatic conditions over the duration of the drilling

campaign and associated onshore support activities. The results of the risk assessment are presented in the following sections for those hazards identified as having medium or high vulnerability during the screening stage.

For the purposes of the climate risk assessment, the severity (or magnitude) of impacts should be evaluated against a predefined scale for each identified climate hazard. It is important that the selected methodology clearly defines the assessment scale used to determine the severity or magnitude of impacts and explains the criteria associated with each rating category. The scale adopted should be proportionate to the characteristics, scale and operational context of the Project. Each severity category should be supported by a descriptive definition; for example, where a rating such as “catastrophic” is used, its implications for the specific Project should be explicitly defined.

Potential consequences may relate to damage or disruption affecting physical assets and operations, occupational health and safety, environmental and social receptors (including impacts on vulnerable groups), economic performance, and other relevant aspects of Project implementation and operation.

For the purposes of the present assessment, the severity of consequences arising from each climate hazard has been evaluated qualitatively, considering the temporary nature of the Asopus-1 exploration drilling campaign, the offshore location of the well, the limited duration of activities, and the existing technical and operational controls incorporated into the Project design. The assessment considers not only direct effects on Project infrastructure and operations, but also potential indirect, secondary and cumulative consequences, including disruption to logistics and marine operations, health and safety implications for personnel, and potential environmental incidents associated with extreme weather conditions.

For the implementation of the risk assessment, a quantitative scale has been defined for the probability of occurrence of climate-related hazards, as well as a severity (magnitude) scale for their potential impacts, in accordance with the provisions of the Climate Resilience Assessment Framework for Infrastructure Projects<sup>61</sup>. The following tables present the calibration of the probability scale for the occurrence of climate hazards within the Project context, and the calibration of the severity scale of impacts. The subsequent section provides the resulting risk evaluation based on the combination of these parameters.

**Table 10-13: Probability of Occurrence Scale (Climate-Related Hazards)**

| LIKELIHOOD     | RATING | DESCRIPTION / QUANTITATIVE ESTIMATION                         |
|----------------|--------|---------------------------------------------------------------|
| Rare           | 1      | 5% likelihood of occurrence over the lifetime of the Project  |
| Unlikely       | 2      | 20% likelihood of occurrence over the lifetime of the Project |
| Moderate       | 3      | 50% likelihood of occurrence over the lifetime of the Project |
| Likely         | 4      | 80% likelihood of occurrence over the lifetime of the Project |
| Almost certain | 5      | 95% likelihood of occurrence over the lifetime of the Project |

<sup>61</sup> Interim Framework for the Assessment of Climate Resilience of Infrastructure Projects submitted for co-financing under ESF+ 2021–2027 programmes, Ministry of Finance, General Secretariat for Public Investments and ESF, National Coordination Authority, General Secretariat for Public Investments and ESF, Ministry of Development and Investments, December 2022.

|               |   |                                                                                                                                                   |
|---------------|---|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Insignificant | 1 | Insignificant impact that can be absorbed through normal activity                                                                                 |
| Minor         | 2 | An adverse event that affects normal activity, resulting in localized impacts                                                                     |
| Moderate      | 3 | A serious event that requires additional emergency business continuity actions, resulting in moderate impacts                                     |
| Major         | 4 | A critical event that requires emergency actions, resulting in significant, widespread, or long-term impacts                                      |
| Catastrophic  | 5 | Disaster with the potential to lead to shut down or collapse or loss of the asset / network, resulting in significant harm and widespread impacts |

Having assessed the likelihood and the impact of each hazard, the significance level of each potential risk can be estimated by combining the two factors. The risks can be plotted on a risk matrix (as part of the overall project risk assessment) to identify the most significant potential risks and those where adaptation measures need to be taken.

### Risk = Likelihood x Impacts

The outcome of the risk assessment can be summarised in a table presenting the likelihood of occurrence and the magnitude (severity) of impacts associated with the key climate-related hazards. The table identifies the assessed hazards and indicates for which of them the combination of likelihood and severity requires the implementation of adaptation measures, as presented in the following table. The risk scale is subsequently expressed in terms of significance levels for each risk score. The different levels of significance (negligible, low, moderate, significant, and very significant) are represented using a colour-coded scale, where green indicates negligible significance and red indicates the highest level of significance, corresponding to the greatest risk.

Table 10-15: Risk Scale

| CONSEQUENCE<br>SEVERITY OR<br>MAGNITUDE | LIKELIHOOD | RARE | UNLIKELY | MODERATE | LIKELY | ALMOST<br>CERTAIN |
|-----------------------------------------|------------|------|----------|----------|--------|-------------------|
|                                         |            | 1    | 2        | 3        | 4      | 5                 |
| INSIGNIFICANT                           | 1          | 1    | 2        | 3        | 4      | 5                 |
| MINOR                                   | 2          | 2    | 4        | 6        | 8      | 10                |
| MODERATE                                | 3          | 3    | 6        | 9        | 12     | 15                |
| MAJOR                                   | 4          | 4    | 8        | 12       | 16     | 20                |
| CATASTROPHIC                            | 5          | 5    | 10       | 15       | 20     | 25                |

Table 10-16: Qualitative description of climate risk scale

| RISK SCALE |               | DESCRIPTION                                                                                                   |
|------------|---------------|---------------------------------------------------------------------------------------------------------------|
| 1-3        | Insignificant | No risk mitigation measures required                                                                          |
| 4-6        | Low           | Need for risk mitigation measures (standard good practice measures) depends on project-specific circumstances |
| 7-10       | Medium        | Need for risk mitigation measures depends on project-specific circumstances                                   |
| 11-19      | High          | Risk mitigation measures are recommended                                                                      |
| 20-25      | Extreme       | Risk mitigation measures are required                                                                         |

The results of vulnerability analysis (Table 10-12) indicate that Medium or High levels of vulnerability may be identified for certain climate-related hazards. Consequently, a risk assessment is carried out for each of these hazards.

Table 10-17: Likelihood of Climate Related Hazards

| CLIMATE-RELATED HAZARDS                                      | LIKELIHOOD RATING |   | JUSTIFICATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------|-------------------|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cyclones, severe storms, hurricanes                          | Rare              | 1 | Extreme cyclonic systems in the Mediterranean (Medicanes) are infrequent and do not exhibit a regular seasonal pattern in the Ionian offshore area. Historical climatological datasets indicate that such systems occur episodically, with limited recurrence over decadal timeframes. Therefore, while not impossible, their occurrence within the Project operational period is considered <b>rare</b> .                                                                                                                                                                                        |
| Tornadoes / Extreme winds                                    | Unlikely          | 2 | Tornado-type vortices in Greece are documented but remain highly localized, short-duration phenomena. Offshore occurrence is even less frequent than on land due to reduced convective triggering mechanisms over open water. Consequently, the probability of direct impact on offshore operations is assessed as <b>rare</b> .                                                                                                                                                                                                                                                                  |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | Moderate          | 3 | The Project onshore support base (Port of Igoumenitsa) is located within APSFR EL05APSFR008 (Kalamas river downstream and coastal zone system). Flood hazard mapping confirms exposure to riverine and coastal flooding under multiple return periods (T=50, T=100, T=1000 years), as well as pluvial flooding under intense rainfall events. Increases in extreme precipitation trends in western Greece are observed, therefore the probability of flooding affecting operational areas during the Project lifetime is conservatively assessed as <b>moderate</b> for risk assessment purposes. |
| Changes in wind characteristics                              | Likely            | 4 | Climate projections for the Mediterranean indicate potential changes in wind regimes, including alterations in storm track variability, seasonal wind distribution and increased frequency of short-duration high-wind events. Given the short duration of the drilling campaign, the <b>likely</b> rating conservatively reflects exposure to hazardous wind conditions during the operational period rather than longer-term changes in the regional wind regime.                                                                                                                               |
| Sea level rise                                               | Rare              | 1 | Sea level rise is a climatic trend confirmed by regional Mediterranean observations and projections. For the 67-day drilling campaign, sea level rise is considered a long-term climatic trend with no measurable variation over the project duration. Consequently, exposure to this hazard during the operational timeframe is assessed as <b>rare</b> .                                                                                                                                                                                                                                        |

Table 10-18: Severity of Climate Related Hazards

| CLIMATE-RELATED HAZARDS                                      | SEVERITY RATING |   | JUSTIFICATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------|-----------------|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cyclones, severe storms, hurricanes                          | Major           | 4 | Should such an event occur, offshore drilling operations using a MODU and support vessels would be exposed to significant operational disruption, including suspension of activities, relocation of vessels, and potential risk to marine operations. However, due to standard offshore safety protocols, forecasting systems, and emergency disconnect procedures, impacts are expected to remain within controlled operational disruption rather than catastrophic failure, thus classified as <b>major</b> . |
| Tornadoes / Extreme winds                                    | Moderate        | 3 | Extreme wind events can temporarily exceed operational thresholds for lifting, drilling, and vessel transfer operations, leading to suspension of activities and potential safety risks during marine operations. However, the presence of strict operational wind limits, dynamic positioning systems, and shutdown procedures limits escalation, resulting in <b>moderate</b> consequences.                                                                                                                   |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | Major           | 4 | Flooding could result in direct inundation of logistics areas, temporary shutdown of port operations, damage to equipment and materials, disruption of supply chain continuity, and restricted access to offshore support infrastructure. Due to the concentration of critical logistics at a single coastal hub, consequences are assessed as <b>major</b> , reflecting potential multi-day to multi-week operational disruption.                                                                              |
| Changes in wind characteristics                              | Moderate        | 3 | Changes in wind characteristics primarily affect operational planning, vessel routing, and weather windows for offshore activities. While they may reduce operational efficiency and increase standby time, they do not generally result in structural damage due to operational limits and marine safety procedures. Therefore, consequences are classified as <b>moderate</b> operational impact rather than safety-critical failure.                                                                         |
| Sea level rise                                               | Minor           | 2 | For the Project, impacts are primarily associated with the onshore logistics base and port infrastructure through potential changes in baseline flood levels, increased storm surge amplification, and drainage capacity exceedance. However, due to the temporary nature of drilling activities and existing port adaptation capacity, consequences are assessed as <b>minor</b> , particularly within the Project timeframe.                                                                                  |

Table 10-19: Climate risk assessment for the Project

| CLIMATE-RELATED HAZARDS                                      | VULNERABILITY | LIKELIHOOD |   | CONSEQUENCE SEVERITY OR MAGNITUDE |   | RISK ASSESSMENT |               |
|--------------------------------------------------------------|---------------|------------|---|-----------------------------------|---|-----------------|---------------|
| Cyclones, severe storms, hurricanes                          | Medium        | Rare       | 1 | Major                             | 4 | 4               | Low           |
| Tornadoes / Extreme winds                                    | Medium        | Unlikely   | 2 | Moderate                          | 3 | 6               | Low           |
| Flooding (coastal, fluvial, pluvial or groundwater flooding) | High          | Moderate   | 3 | Major                             | 4 | 12              | High          |
| Changes in wind characteristics                              | High          | Likely     | 4 | Moderate                          | 3 | 12              | High          |
| Sea level rise                                               | Medium        | Rare       | 1 | Minor                             | 2 | 2               | Insignificant |

### 10.1.2.3.3 Measures to enhance climate change adaptation - residual risk

For the purposes of climate vulnerability risk assessment, adaptation and mitigation measures are considered for climate-related hazards assessed as having at least a medium level of risk. This approach focuses on hazards that may result in non-negligible residual risk if no additional measures are implemented. Consequently, hazards assessed as Low risk are not further developed within the risk management framework, as the associated risks are considered sufficiently addressed through the inherent resilience of the Project design and standard good engineering practice. The objective of this stage is to ensure that, for all relevant medium and high climate-related risks, appropriate adaptation measures are identified and integrated where necessary, to achieve the greatest possible reduction of residual risk across the Project lifecycle.

With regard to flooding risk (coastal, fluvial, pluvial, or groundwater flooding), the onshore logistics base is located within the APSFR EL05APSFR008 (Kalamas river delta and coastal zone of Igoumenitsa). The Project is potentially exposed to riverine, coastal, and pluvial flooding under both current and future climate conditions. Adaptation is therefore focused on reducing exposure of critical assets and ensuring operational continuity under extreme events. Key measures include the following:

- Elevation of sensitive equipment, electrical installations, and hazardous materials above the relevant design flood levels, including consideration of extreme return periods where appropriate.
- Site layout is optimised to avoid, where practicable, areas identified as high flood hazard within the mapped flood risk zones.
- Temporary Project facilities, equipment and hazardous materials will, where practicable, be located or secured with due regard to mapped flood-risk areas and applicable port requirements.
- Project logistics arrangements will consider available flood warnings, access restrictions and temporary disruption at the existing port facilities.
- Ground-level structures are designed using flood-resilient materials and construction techniques to minimise damage in the event of inundation, while modular or raised platforms are adopted for particularly sensitive operational components.
- A robust surface water management system is implemented, designed to accommodate intense precipitation events with appropriate climate change allowances. This includes appropriately sized drainage infrastructure, regular maintenance to prevent blockage, and the incorporation of attenuation or temporary storage capacity where necessary to reduce peak runoff. Measures to prevent backflow from coastal or fluvial sources, such as non-return valves or passive flood protection elements, are also integrated where relevant.
- From an operational perspective, flood resilience is further reinforced through emergency preparedness procedures, including early warning systems, defined shutdown and evacuation protocols, and the ability to rapidly secure or relocate mobile equipment and materials in advance of extreme weather events.
- The logistics system is designed with redundancy where feasible, ensuring alternative access routes in the event of temporary flooding-related disruption.

The Project area, particularly offshore operations, is subject to variable wind regimes, which may become more pronounced under future climate conditions, including changes in average wind patterns and an increased frequency of extreme wind events. Adaptation in this context is primarily operational and safety-

driven, focusing on maintaining safe working conditions and minimising downtime rather than permanent structural modification.

- Offshore operations are therefore governed by clearly defined wind operational limits, which determine safe thresholds for lifting operations, vessel transfers, and dynamic positioning activities. These thresholds are supported by real-time meteorological forecasting and decision-support systems, allowing proactive planning and avoidance of adverse conditions.
- The MODU and associated marine vessels are designed and operated in accordance with applicable international offshore standards, ensuring adequate structural resilience to extreme wind loads and maintaining safety margins for equipment securing and deck operations.
- Operational continuity is further enhanced through flexible scheduling of marine and helicopter transfers, allowing activities to be adjusted in response to changing wind conditions.
- Where necessary, contingency arrangements are in place to temporarily suspend operations during periods of unsafe meteorological conditions, with minimal disruption to overall drilling campaign progression.

Collectively, these measures ensure that wind-related climate variability is effectively managed through a combination of engineering standards, operational controls, and forecasting capability, rather than reliance on fixed structural adaptation.

Proposed measures to achieve additional adaptation and increased resilience to climate change are listed in Table 10-20 and the residual risk is reassessed.

**Table 10-20: Climate Change Adaptation Measures and Residual Risk for the Project**

| CLIMATE-RELATED HAZARDS                                      | RISK ASSESSMENT |      | CLIMATE CHANGE ADAPTATION MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | RESIDUAL RISK |   |

| Changes in wind characteristics | 12              | High | <p>Operational design and marine safety measures</p> <ul style="list-style-type: none"> <li>Apply operational limits (wind thresholds) for MODU operations, lifting activities, and vessel transfers.</li> <li>Use real-time meteorological forecasting systems integrated with offshore decision support tools.</li> <li>Ensure that all marine operations follow weather downtime planning procedures to avoid exposure during high wind conditions.</li> </ul> <p>Structural and equipment resilience</p> <ul style="list-style-type: none"> <li>Ensure that MODU and offshore support vessels comply with relevant IMO and class society extreme wind design standards.</li> <li>Secure all deck equipment using storm securing arrangements designed for extreme wind events.</li> <li>Design lifting and crane operations with wind load safety margins consistent with offshore engineering standards.</li> </ul> <p>Logistics and operational continuity</p> <ul style="list-style-type: none"> <li>Maintain flexible scheduling of offshore transfers and helicopter operations to accommodate wind variability.</li> <li>Identify practicable logistics contingency arrangements to manage potential disruption due to wind-induced port or offshore access constraints.</li> <li>Ensure contingency planning for temporary suspension of operations during extreme wind events.</li> </ul> | Low           | 6 |

Based on the results of the above analysis, with the adoption of the applicable adaptation measures, the maximum possible reduction of the residual risk is achieved, and the entirety of the significant inherent risks becomes fully controllable and manageable. However, relevant weather forecasts and warnings will be monitored throughout the drilling campaign, and operational controls will be adjusted where necessary through established Project and contractor procedures.

### 10.1.3 Impacts on morphological and topological characteristics

#### 10.1.3.1 Morphology

According to the baseline geohazards assessment of the ESBS (Annex 02), the surveyed area around the proposed Asopus-1 well is characterised by rough seafloor and complex morphology associated with exposed mass transport deposit (MTD) material. The planned well location lies within a low-reflectivity groove covered by fine sediments, with a gentle seabed gradient of approximately 1.3°. No fault scarp morphologies, active seabed deformation or evidence of remobilisation of the underlying MTD unit have been identified within the 500 m radius area.

### 10.1.3.1.1 Drilling preparation and mobilisation phase

During the mobilisation phase, no drilling operations are undertaken and therefore no discharge of drilling fluids, cuttings, cement, or any other materials to the marine environment occurs. The only offshore mobilisation activities consist of the transit and positioning of the MODU and its associated support vessels at the drilling location. These activities are entirely navigational and do not involve any direct interaction with the seabed. The MODU will be positioned using dynamic positioning systems rather than anchoring, meaning that there is no physical seabed contact or mechanical disturbance of sediments.

As a result, there is no pathway for the mobilisation phase to induce morphological change. Vessel movements may generate short-lived hydrodynamic disturbances in the water column; however, these are fully transient and dissipate rapidly without influencing seabed structure or sediment stability. No erosion, scour development, sediment redistribution, or alteration of seabed micro-topography is expected. Consequently, offshore morphological impacts during mobilisation are considered negligible.

Onshore mobilisation activities are restricted to the use of the existing Port of Igoumenitsa as a logistics base for loading, staging, and dispatch of equipment and personnel. These activities take place entirely within an already industrialised and permanently modified coastal environment. No construction works, dredging, shoreline reinforcement, land reclamation, or excavation activities are required in support of the Project.

Because the port area is structurally fixed and geomorphologically inactive in natural terms, Project activities do not interact with active sediment transport systems or coastal erosion processes. Accordingly, there is no influence on coastal morphology, shoreline configuration, or terrestrial landform stability. Utility connection works may involve minor and localised ground disturbance within existing port infrastructure in the highly modified port environment. Considering also the relatively limited scale of works, no significant impacts on terrestrial morphology are anticipated, and any effects will be temporary and fully reversible.

In summary, with regard to their significance, the impacts on morphology during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on morphology            |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |

### 10.1.3.1.2 Exploration drilling operations phase

Limited morphological interaction with the marine environment may occur during drilling, primarily as a consequence of controlled operational discharges. These include the discharge of water-based drilling muds and drill cuttings during both riserless and riser drilling sections, cement residues associated with casing

operations, minor bulk material losses such as barite and cement fines, and small volumes of water-soluble BOP hydraulic fluids.

In particular, the riserless section involves seabed-level discharge of drilling cuttings and water-based muds. During this phase, approximately several hundred tonnes of cuttings and drilling fluids may be released directly at or near the seabed. Once the marine riser is installed, subsequent discharges occur at approximately 12 m below sea level, allowing partial dilution within the water column before sedimentation. Although the total mass of discharged material over the drilling campaign is not negligible, the physical nature of the materials is predominantly fine-grained, unconsolidated and low-toxicity, consisting largely of seawater, clay minerals, carbonate particles, barite (if used since it is a contingency chemical) and biodegradable additives selected and discharged in accordance with applicable chemical approval and discharge requirements.

From a morphological perspective, these discharges do not result in permanent seabed modification. Instead, they may give rise to a localised, low-relief depositional footprint around the well location, typically expressed as a thin layer of redistributed sediments and cuttings. This represents a physical alteration of surface sediment characteristics rather than a modification of seabed landform or marine geomorphological processes.

Cuttings dispersion modelling (Annex 07) undertaken for the Asopus-1 exploration well supports this assessment. Deterministic simulations were run for two representative seasonal scenarios: Season 1, corresponding to the most frequent current conditions during October to March, and Season 2, corresponding to higher-intensity current conditions during April to September. The modelling identified grain-size change as the primary contributor to sediment-related risk, followed by effective depositional thickness. Sediment screening-threshold exceedance was predicted to extend up to approximately 283 m to the south-west under Season 1 conditions and up to approximately 397 m under Season 2 conditions. The modelling represents a conservative design-envelope case in which all modelled primary and contingency chemicals are assumed to be used at their maximum stated concentrations and is therefore not representative of the expected operational chemical-use profile. After 10 years of model run on a conservative scenario where all the primary and contingency chemicals are used to the maximum stated concentrations, the maximum affected distance was predicted to reduce to approximately 213 m and 287 m, respectively. In both scenarios, the maximum modelled seabed area exceeding the screening threshold was estimated at approximately 2.75 ha.

These modelling results indicate that the morphological effect of drilling discharges will remain confined to the vicinity of the well location and will be driven mainly by physical sediment change rather than chemical toxicity. The modelled risks are localised in the discharge area, while water-column risks are predicted to cease within a few days after the end of discharges. The footprint is therefore spatially limited and does not indicate a potential for large-scale seabed modification or wider marine geomorphological change.

Hydrodynamic conditions at the drilling location will further contribute to the dispersion and redistribution of discharged material. Bottom currents and episodic marine processes may promote resuspension and reworking of fine sediments, preventing long-term consolidation of deposits. As a result, any seabed modification is expected to be temporary to medium-term in nature and subject to natural sedimentary rebalancing processes.

Cement discharges are generally of lower morphological relevance, as most cement is retained within the wellbore annulus, with only limited excess volumes potentially reaching the seabed. These materials are not expected to form persistent geomorphological structures. Similarly, BOP hydraulic fluid releases are water-soluble and occur in small volumes, with no capacity to influence seabed morphology.

Importantly, no seabed excavation, trenching, anchoring systems, subsea infrastructure or cuttings piling infrastructure is associated with the Project. Therefore, there will be no permanent alteration of seabed form, slope configuration or marine geomorphological structure. The morphological effect is strictly confined to temporary sediment redistribution and localised deposition within the operational footprint.

With regard to drilling contingency activities, potential impacts on morphology would be limited to the seabed in the immediate vicinity of the well location and any replacement or sidetrack location within the surveyed area. Re-spudding may require repetition of early well construction activities, particularly riserless drilling, resulting in additional cuttings and cement deposition on the seabed. Sidetracking may also increase the volume of cuttings and drilling residues, although generally to a lesser extent than a full re-spud. An Emergency Disconnect Sequence could result in the localised discharge of riser contents (drilling fluids and cuttings) at the seabed. Contingent cementing could also generate additional cement residues if excess cement or washout material is discharged. These effects may locally alter seabed surface characteristics through deposition, smothering or minor sediment displacement. However, they would not alter regional seabed morphology or coastal geomorphological conditions.

Onshore support operations at the Port of Igoumenitsa include equipment handling, logistics, storage, and vehicle movements within existing port infrastructure. These activities do not involve any excavation, ground preparation, or modification of coastal structures. All operational surfaces are already paved or industrially developed, meaning that no interaction with natural geomorphological processes occurs.

Furthermore, there is no requirement for dredging, shoreline stabilization works, or expansion of port facilities to accommodate the project. Consequently, there is no mechanism through which the drilling phase could influence coastal erosion patterns, sediment transport dynamics, or terrestrial landform evolution. Onshore morphological impacts during drilling are therefore negligible.

In summary, with regard to their significance, the impacts on morphology during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN=1-2), localised to the well area (EX=1-2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with no synergistic effects (SI=1), direct (EF=4), either continuous or occasional depending on the activity (PR=1-4), with short-term recovery after completion of drilling (MC=2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

### 10.1.3.1.3 Demobilisation and abandonment phase

During demobilisation and well abandonment activities, offshore morphological impacts remain limited to residual and secondary effects associated with the cessation of drilling operations and the execution of well plug and abandonment (P&A) procedures. These may include additional volumes of water-based mud displacement, minor cement residues, and small-scale sediment disturbance associated with operational clean-up activities.

During the well plug and abandonment phase, cement plugs are installed within the wellbore to provide permanent isolation of geological formations and ensure long-term well integrity. These activities are undertaken entirely within the drilled well and do not require excavation, dredging, trenching, or any other direct modification of the seabed. Consequently, the installation of cement plugs itself does not result in any significant alteration of seabed morphology.

In line with industry practices for deepwater drilling, the wellhead will be left in place. Retention of the wellhead does not alter the abandonment status of the well. The well will be rendered non flowing and environmentally secure, with no connection to the reservoir, with permanent well barriers installed and verified in accordance with the approved abandonment programme and applicable regulatory requirements. All temporary subsea infrastructure (including the BOP, marine riser, and transponders) will be removed, and no production facilities, pipelines, control umbilical, or surface installations will be installed. Based on the current design, the permanent physical footprint on the seabed associated with the exploration activity is expected to be less than 1 m<sup>2</sup>. The physical seabed footprint of a retained wellhead is small and does not require routine inspection, operations, or support activities. Retaining the wellhead avoids additional seabed disturbance and vessel activity that would otherwise be required for immediate removal followed by potential future re-entry, if subsequently required and authorised, and is therefore considered a proportionate measure.

Limited discharges of residual cement slurry and water-based drilling fluids may occur during well abandonment operations, primarily during cementing clean-up, well displacement, and circulation activities. These discharges may lead to minor and highly localized deposition of fine materials on the seabed in the immediate vicinity of the well site. However, the volumes involved are relatively small compared with natural sediment transport processes in the deep offshore environment, and the discharged materials are expected to disperse and become incorporated into the surrounding sediments over time.

Demobilisation activities do not introduce new physical interventions to the seabed beyond those already experienced during drilling. Instead, they primarily interact with previously disturbed sediments within the existing operational footprint. Any additional sediment resuspension or redistribution is therefore a continuation of earlier processes rather than the creation of new morphological change.

The absence of permanent seabed infrastructure ensures that no residual geomorphological features of engineering significance, such as foundations or cuttings piles, remain after completion of the project. Natural sediment transport processes will continue to act on the seabed, progressively re-establishing equilibrium conditions over time.

Onshore demobilisation activities consist of the removal, retention or asset transfer, as agreed with the Port operator, of temporary equipment and the reinstatement or other agreed handback of operational areas within the Port of Igoumenitsa. These actions occur entirely within an already modified industrial port environment and do not involve any physical alteration of landforms or coastal structures.

No demolition of permanent infrastructure, excavation of soil, or alteration of shoreline configuration is required. Therefore, there is no pathway for residual morphological impact. The port environment remains structurally unchanged following completion of activities, and no effects on coastal geomorphology or sedimentary processes are expected.

In summary, with regard to their significance, the impacts on morphology during the demobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on morphology                    |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |            |                            |                     |

### 10.1.3.2 Landscape

#### 10.1.3.2.1 Drilling preparation and mobilisation phase

During the mobilisation phase, visual impacts will arise from the transit and positioning of the MODU, support vessels and helicopters associated with the Project. However, the drilling location is situated approximately 44 km offshore, well beyond the visual horizon from the mainland coastline under normal atmospheric conditions. Consequently, the MODU and associated vessels are not expected to be visible from coastal receptors, including settlements, tourist areas or recreational viewpoints along the Epirus coastline.

Temporary visual effects may occur within the Port of Igoumenitsa during mobilisation activities associated with the establishment of the shore base. These activities include the arrival of equipment, temporary storage units, cargo handling equipment and increased vessel movements within the existing port area. These activities take place entirely within an established commercial port characterised by intensive industrial and transport activities. The introduction of temporary project-related equipment will not substantially alter the existing landscape character.

In summary, with regard to their significance, the impacts on landscape during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on landscape                                                                                                            |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |
|---------------------------------------------------------------------------------------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|------------|----------------------------|---------------------|
| Project Activities / Elements                                                                                                   | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |            | Valued Receptor Assessment | Impact Significance |
| Installation of wharf crane (if applicable), utility connections, prefabricated office units, welfare and sanitation facilities | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20                    | Negligible | Medium                     | NEGLECTIBLE         |

### 10.1.3.2.2 Exploration drilling operations phase

During drilling operations, the principal offshore visual element will be the presence of the MODU and associated support vessels at the well location for approximately 67 days. The MODU is a large industrial structure and will be illuminated during night-time operations for safety and operational reasons.

Nevertheless, due to the substantial distance from the coast (>44 km), the MODU is not expected to be visible from onshore receptors under normal conditions. Consequently, no significant effects on coastal landscape character, scenic quality, tourism resources or designated landscape areas are anticipated.

The operation of helicopters between the shore base and the MODU may generate occasional visual disturbance. However, helicopter movements will be intermittent, short in duration and limited to established aviation routes. These flights are not expected to result in significant visual intrusion, considering the existing transport and port-related activities in the area.

Visual impacts associated with shore base operations will include the temporary presence of containers, equipment, waste skips, parked vehicles and cargo handling activities within the Port of Igoumenitsa. As the Project will utilise existing port facilities and no permanent infrastructure will be constructed, the overall appearance and landscape character of the port area will remain unchanged.

The Port of Igoumenitsa constitutes a highly modified urban-industrial landscape where shipping, cargo handling and logistics activities already form dominant visual components. The temporary increase in operational activity associated with the Project is therefore considered compatible with the existing landscape character and visual baseline.

In summary, with regard to their significance, the impacts expected on landscape during the drilling operations phase are assessed as negative (-), of negligible intensity (IN=1), limited to the offshore operational area (EX=2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term reversible following cessation of activities (RV=1), non-synergistic (SI=1), direct (EF=4), continuous during

operations (PR=4), restored immediately after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Impacts on Landscape                                           |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |
|----------------------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|-----|----------------------------|---------------------|
| Project Activities / Elements                                  | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |     | Valued Receptor Assessment | Impact Significance |
| MODU safety exclusion zone and support/supply vessel transfers | -          | 1              | 2           | 4           | 1                | 1                  | 1            | 4           | 1                | 1             | 1                 | 21                    | Low | Low                        | NEGLECTIBLE         |

### 10.1.3.2.3 Demobilisation and abandonment phase

Demobilisation activities involve the departure of the MODU, support vessels and associated marine assets from the drilling location following completion of drilling and well abandonment operations. These activities do not introduce additional visual elements beyond those already present during the operational phase and are of short duration.

Following completion of demobilisation, no permanent offshore infrastructure will remain at the well location, other than the retained wellhead, which will be located on the seabed and will not affect visual conditions. The removal of the MODU and associated vessels will restore baseline visual conditions.

Demobilisation of the temporary shore base will involve the removal of containers, equipment, temporary storage areas and ancillary facilities from the Port of Igoumenitsa. Since no permanent structures will have been constructed, the port area will revert to its pre-project condition immediately following completion of activities. For the Port of Igoumenitsa, this positive effect would be associated with the removal of temporary containers, storage areas and equipment and the cessation of increased logistics activities and vehicle movements. Overall, the demobilisation and abandonment phase can be considered to generate a minor positive impact on landscape and visual amenity, because all temporary Project infrastructure and activities cease and baseline conditions are restored.

In summary, with regard to their significance, any negative (-) visual impacts during demobilization will be of negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on landscape                       |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

## 10.1.4 Impacts on geological, tectonic, and soil characteristics

### 10.1.4.1 Geology / marine geology

#### 10.1.4.1.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, no significant impacts on geology or marine geology are expected. Offshore activities will be limited to the transit and positioning of the MODU and support vessels at the well location. As the drillship will operate using dynamic positioning and no anchoring is planned, there will be no direct physical disturbance of seabed sediments, sub-seabed formations or marine geological structures during mobilisation.

Onshore mobilisation activities will be confined to existing paved areas within the Port of Igoumenitsa and Corfu airport facilities. No land take, excavation, quarrying, dredging, reclamation or modification of natural geological formations is required. Any temporary installation of offices, welfare units, storage areas or utility connections will be undertaken within already modified operational areas and will not affect geological conditions.

In summary, with regard to their significance, the impacts on geology / marine geology during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

#### 10.1.4.1.2 Exploration Drilling Operations Phase

During the offshore exploration drilling phase, the Project will interact directly with the geological environment below the seabed, through the drilling of the Asopus-1 exploration well. This interaction will involve the mechanical penetration of geological formations, removal of drilled material as cuttings, installation of casing strings, cementing and formation evaluation activities. These effects will be confined to the wellbore and its immediate surroundings and will not result in any measurable alteration of regional geological, tectonic or marine geological conditions.

The drilling activity will create a borehole through the subsurface formations. The Asopus 1 exploration well will be drilled using established offshore exploration drilling practices, progressing sequentially from shallow seabed sections to the planned final depth. Well construction will be carried out in accordance with the HEREMA accepted Notification of Well Operations (NoWO), maintaining well control and integrity throughout the operation. The operations include riserless drilling of shallow top hole sections, during which water-based drilling fluids and rock cuttings are discharged at the seabed, and riser based drilling, following installation of the marine riser and blowout preventer (BOP), during which drilling returns are routed to the drillship.

Cuttings generated during drilling will represent the physical removal of a small volume of geological material relative to the scale of the surrounding formations. The effect is therefore highly localised and limited to the well path.

Marine geological effects at the seabed will be mainly associated with the top-hole sections, riserless drilling activities, placement of the wellhead and BOP system, and the controlled discharge of water-based drilling fluids and cuttings. These activities may result in a localised depositional footprint of cuttings and fine mineral material around the well centre. However, the materials are expected to consist primarily of naturally occurring geological formations and water-based drilling fluids, and the resulting seabed interaction will be limited in area and thickness.

The Project does not involve hydrocarbon production, reservoir depletion, underground storage, large-scale fluid injection or extraction activities that could affect regional geomechanical conditions or induce seismicity.

No dredging, trenching, seabed levelling, anchoring system, pipeline installation or permanent offshore production infrastructure is proposed. Therefore, impacts on marine geology will not involve large-scale seabed excavation or permanent modification of the seabed geological environment. Cementing operations will be limited to well construction and zonal isolation, with cement retained primarily within the wellbore and annular spaces. Any minor seabed interaction from excess cement or drilling-related material will remain localised to the well area.

The well design, casing programme, cementing strategy and well control procedures will be implemented to maintain wellbore stability and prevent uncontrolled interaction between geological formations. These measures will be designed and implemented to manage the risk of formation instability, cross-flow or unintended subsurface migration of fluids.

In summary, with regard to their significance, the impacts on geology / marine geology during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN=1-2), localised to the well area (EX=1), immediate (MO=4), temporary or permanent throughout the drilling period, depending on the activity (PE = 1 - 4), irreversible as the well will be left in place (RV= 1 - 4), with no synergistic effects (SI=1),

direct (EF=4), irregular (PR=1), with short-term recovery after completion of drilling (MC=2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

| Impacts on geology / marine geology                                                 |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.4.1.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, potential impacts on geology and marine geology will be associated mainly with plug and abandonment activities, cement plug installation, circulation and displacement of well fluids, ROV inspections and final departure of the MODU and support vessels. These activities will be undertaken within the already drilled well and will not create new geological disturbance beyond the existing wellbore.

Cement plugs and other permanent well barriers will be installed to isolate geological formations and ensure long-term well integrity. This represents a controlled engineering measure intended to stabilise and secure the well rather than an adverse geological impact. The abandonment programme will be designed to prevent fluid movement between formations and between the subsurface and seabed, thereby protecting the marine geological environment from future uncontrolled pathways.

As the wellhead will be left in place, no wellhead cutting or seabed excavation associated with wellhead removal will be undertaken. Therefore, no additional seabed disturbance from cutting, sediment resuspension or removal of seabed equipment is expected. ROV post-operation surveys will be observational and will not materially disturb seabed sediments or geological features.

Following completion of plug and abandonment and departure of the MODU, no further Project activities capable of affecting geology or marine geology will occur. The remaining subsurface infrastructure will be confined to the wellbore and designed to remain stable over the long term. Accordingly, impacts on geology and marine geology during demobilisation and abandonment are expected to be highly localised and controlled through standard well abandonment procedures.

In summary, with regard to their significance, the impacts on geology / marine geology during the demobilisation phase are assessed as negative (–), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on geology / marine geology        |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.4.2 Slope stability

According to the baseline geohazards assessment of the ESBS (Annex 02), the well is located in approximately 842.5 m water depth on a gentle local slope of approximately 1.3°. Although harder mass transport deposit (MTD) sediment bodies within the 500 m radius area create localised steeper flanks where slope values may exceed 10°, the well location itself falls within a groove of fine sediments, and no evidence of active seabed deformation, fault scarps or remobilisation of the underlying MTD gravity unit has been identified.

Considering the regional spatial datasets and predictive models, the assessment of the Asopus-1 well location indicates a low susceptibility to gravitative mass movements. Based on the relatively gentle local slope gradients, it is expected that the probability of encountering submarine landslides or gravitative mass movements at the Asopus-1 well location is low.

##### 10.1.4.2.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, no impacts on slope stability are expected. Offshore activities will be limited to the transit of the MODU and support vessels to the well location and the positioning of the drillship using dynamic positioning. No anchoring, seabed excavation, dredging, trenching, piling or placement of heavy permanent structures on the seabed will be undertaken during this phase. Therefore, there will be no physical mechanism capable of destabilising seabed sediments, submarine slopes or marine geological formations.

Any temporary utility connections required at the shore base will use existing infrastructure and are not expected to require excavation or modification of natural ground conditions. Installation of temporary utility connections at the shore base may involve minor surface-level works or shallow tie-ins to existing electricity and telecommunications networks within the Port of Igoumenitsa. Any activity will be undertaken within

existing paved port areas and will not require slope cutting, deep excavation, retaining structures or modification of natural ground conditions.

In summary, with regard to their significance, the impacts on slope stability during the mobilisation phase are assessed as negative (–), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), restored immediately (MC = 1), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on slope stability       |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |

#### 10.1.4.2.2 Exploration drilling operations phase

During the exploration drilling operations phase, potential interactions with slope stability are limited to the immediate well location and surrounding seabed. The main relevant activities are drilling of the well, installation of the wellhead and casing, operation of the BOP and riser system, and the discharge of water-based drilling fluids and cuttings, particularly during riserless drilling.

The Project will not involve seabed excavation, trenching, dredging, anchoring, pipeline installation or construction of permanent subsea infrastructure. The MODU will remain dynamically positioned and will not impose anchor loads on the seabed. Therefore, the Project is not expected to create significant mechanical disturbance or loading capable of affecting seabed slope stability.

The drilling of the well will penetrate subsurface geological formations, but the disturbance will be confined to the narrow wellbore. The Project does not involve production, reservoir depletion, large-scale fluid injection or underground storage, and therefore it is not expected to alter regional pore pressures, stress conditions or geomechanical stability in a manner that could affect submarine slope stability. Well design, casing installation, cementing and drilling fluid management will be implemented to maintain wellbore integrity and prevent instability within the drilled hole. These measures will reduce the potential for borehole collapse, uncontrolled formation interaction or localised instability around the well.

Riserless drilling may result in localised deposition of cuttings and water-based drilling fluids around the well centre. However, this material will form a limited depositional footprint and is not expected to create sufficient thickness, weight or lateral loading to trigger seabed instability or mass movement. Discharges during riser drilling will occur near the sea surface and will disperse through the water column, with any settled material expected to be thin and spatially limited.

In summary, with regard to their significance, the impacts on slope stability during the drilling operations phase are assessed as negative (–), of negligible to low intensity (IN = 1 – 2), localised to the well area (EX=1), immediate (MO=4), temporary (PE = 1), short-term (RV= 1), with no synergistic effects (SI=1), direct

(EF=4), irregular (PR=1), with short-term recovery after completion of drilling (MC = 1 – 2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

| Impacts on slope stability                                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |  |

#### 10.1.4.2.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, potential interactions with slope stability will be limited to plug and abandonment activities within the existing wellbore. No new drilling, seabed excavation, dredging, trenching, anchoring or wellhead cutting will be undertaken.

Cement plug installation and abandonment activities will occur inside the already drilled wellbore and are intended to isolate geological formations and ensure long-term well integrity. These activities will not modify seabed gradients, disturb submarine slopes or create additional seabed loading. As the wellhead will be left in place, there will be no seabed disturbance associated with wellhead removal.

Following completion of abandonment and departure of the MODU and support vessels, no further Project activities capable of influencing slope stability will remain.

Onshore demobilisation activities will be confined to dismantling and removal of temporary facilities within existing port and airport areas. No ground excavation or modification of natural slopes is required.

In summary, with regard to their significance, the impacts on slope stability during the demobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on slope stability                 |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.4.3 Tectonics and seismicity

The Asopus-1 exploration well is located within the southern part of the Adria Microplate, in the Apulian platform geological unit, within a broader Northern Ionian Sea region characterised by a complex tectonic history and influenced by the wider geodynamic setting of the Eastern Mediterranean. Regional tectonic processes are controlled by major structures including the Hellenic and Calabrian subduction zones, inherited normal faults, tectonic inversion structures and active seismogenic fault systems in the broader area. At the Project location, the local tectonic framework is characterised by a structurally faulted carbonate platform setting, with normal faults forming a horst-and-graben structural pattern and providing accommodation space for overlying sedimentary basins. However, the well will be located in a structurally relatively flat, fault-displaced carbonate platform environment and is separated from the active compressive subduction zones that bound the wider Ionian basin.

With regard to seismicity, the Project is located within the broader seismotectonic setting of the Ionian basin, which is influenced by the slow convergence of the African (Nubian) and Eurasian plates and by the counterclockwise rotation of the Ionian–Apulian microplate. The wider region of Western Greece and the Ionian Sea is seismically active, with frequent small to medium earthquakes and occasional strong events associated mainly with active fault systems along the Calabrian Arc and the Hellenic Trench. However, the well location lies on the structurally uplifted Apulian platform, away from the highest concentration of historical earthquake epicentres and active seismogenic faults located along the peripheral tectonic margins. As a result, the site is characterised by weak to moderate background seismicity.

#### 10.1.4.3.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, no impacts on tectonics or seismicity are expected. Activities will be limited to logistics preparation, mobilisation of the MODU and support vessels, and transit and positioning at the well location. These activities do not involve subsurface penetration, reservoir intervention, seabed excavation, blasting, hydraulic stimulation, large-scale fluid injection, hydrocarbon production, reservoir depletion or underground storage.

Onshore mobilisation activities will be confined to existing paved areas within the Port of Igoumenitsa and Corfu airport facilities, and will not involve deep excavation, blasting, quarrying or other works capable of affecting tectonic or seismic conditions.

Accordingly, there is no credible mechanism through which mobilisation activities could modify tectonic structures, affect fault systems, alter regional stress conditions or induce seismic events. Therefore, the mobilisation phase has no credible impact pathway for tectonic conditions, and impacts are assessed as **negligible**.

#### 10.1.4.3.2 Exploration drilling operations phase

During the offshore exploration drilling phase, the Project will interact with the subsurface geological environment through the drilling of an exploration well, casing installation, cementing and formation evaluation. This interaction will be confined to the narrow wellbore and its immediate surroundings. It will not alter regional tectonic structures, fault systems or the broader geological stress regime of the Ionian Sea.

The Project does not include activities commonly associated with induced seismicity or modification of subsurface stress conditions. Drilling fluids will be used for borehole stability and well control. Consequently, the Project is not expected to trigger earthquakes, increase the frequency of seismic events, alter earthquake magnitude, or modify the natural seismic regime of the area.

The well design, mud programme, casing programme, cementing strategy and well control procedures will be implemented to maintain wellbore stability and isolate geological formations. These measures will control the interaction between the well and the surrounding formations and reduce the potential for uncontrolled formation communication or localised instability.

Although the wider Ionian region is tectonically active, tectonic setting is considered a baseline geohazard relevant to Project design, well integrity and operational safety, rather than an environmental receptor likely to be affected by the Project.

Onshore support activities during drilling will be limited to logistics, storage, utility use, waste handling and transport within existing port infrastructure, with no subsurface works or ground interventions capable of modifying tectonic structures or influencing seismicity.

In summary, with regard to their significance, the impacts on tectonics and seismicity during the drilling operations phase are assessed as negative (–), of negligible intensity (IN = 1), localised to the well area (EX=1), immediate (MO=4), temporary (PE = 1), short-term (RV= 1), with no synergistic effects (SI=1), direct (EF=4), irregular (PR=1), with immediate recovery after completion of drilling (MC = 1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Impacts on tectonics and seismicity             |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |
|-------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|----------------------------|
| Project Activities / Elements                   | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) | Valued Receptor Assessment |

#### 10.1.4.3.3 Demobilisation and abandonment phase

During the offshore demobilisation and abandonment phase, interactions with the subsurface will be limited to plug and abandonment activities within the already drilled wellbore. Cement plugs and permanent barriers will be installed to isolate geological formations and secure long-term well integrity. These activities are controlled engineering measures and do not involve any intervention capable of affecting tectonic structures, faults or regional stress conditions.

As the wellhead will be left in place, no wellhead cutting or additional seabed disturbance associated with wellhead removal is expected. Following completion of plug and abandonment, the well will remain isolated by permanent barriers and no further Project activities capable of affecting tectonic conditions will remain.

Onshore demobilisation activities will involve the removal of temporary facilities, equipment and materials from existing port and airport areas and will not involve excavation, blasting, ground loading or any activity capable of affecting tectonic or seismic conditions.

In summary, with regard to their significance, the impacts on tectonics and seismicity during the demobilisation phase are assessed as negative (–), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction effects (SI = 1), with direct effect (EF = 4), discontinuous in nature (PR = 1), characterised by immediate recovery potential (MC = 1), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on tectonics and seismicity      |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |

| Cement plug installation and abandonment | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 1             | 1                 | 19 Negligible         | Medium                     |
|                                          |            |                |             |             |                  |                    |              |             |                  |               |                   |                       | NEGLIGIBLE                 |

#### 10.1.4.4 Soil

##### 10.1.4.4.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, potential impacts on soil will be very limited, as onshore activities will be confined to existing paved areas within the Port of Igoumenitsa and existing facilities at Corfu International Airport. No construction works involving land take, vegetation clearance, earthworks, soil stripping, deep excavation or backfilling are required. The main activities will include preparation of the temporary logistics base, installation of prefabricated units, welfare facilities, temporary fencing, signage, utility connections and loading or staging of equipment and materials.

As these activities will take place within already modified areas, no direct disturbance of natural soils is expected. Minor and localised interaction may occur only where utility connections or installations require limited works within existing paved surfaces. The only potential impact on soil quality would come from the accidental spill of fuels, oils, chemicals or other hazardous materials during equipment mobilisation, temporary storage or handling. However, these risks will be controlled through use of designated storage areas, bunding, spill kits, good housekeeping and immediate spill response procedures.

In summary, with regard to their significance, the impacts on soil during the mobilisation phase are assessed as negative (–), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction effects (SI = 1–2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on soil                                   |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |
|---------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|------------|----------------------------|---------------------|
| Project Activities / Elements                     | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |            | Valued Receptor Assessment | Impact Significance |
| Onshore base equipment and utilities installation | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20                    | Negligible | Low                        | NEGLIGIBLE          |
| Onshore loading/unloading or staging              | -          | 1              | 1           | 4           | 1                | 1                  | 2            | 4           | 1                | 2             | 1                 | 21                    | Low        | Low                        | NEGLIGIBLE          |

#### 10.1.4.4.2 Exploration drilling operations phase

Onshore activities will be limited to logistical support at the Project's shore base at the Port of Igoumenitsa, including storage, vessel support, and coordination activities. No new onshore construction, excavation or disturbance of natural ground is required, and therefore no direct physical impact on soil resources is anticipated. No industrial or maintenance works are planned at the shore base.

Accidental contamination of paved surfaces could occur as a result of minor leaks or accidental releases of fuels, lubricants, chemicals, waste oils, contaminated materials or hazardous materials during handling and temporary storage. If not promptly contained, such releases could create a pathway for contaminants to reach underlying soils through cracks, joints, drainage points or damaged surface areas. However, the Project will implement dedicated chemical and waste management procedures, including segregation of materials, appropriate packaging and labelling, use of bunded or contained storage areas, routine inspection of containers, spill prevention measures and immediate response to any accidental release. Rainfall runoff from operational areas will be managed through the existing port drainage system. These controls will minimise the likelihood of contaminants reaching soil and support the prompt containment and remediation of any incident.

In summary, with regard to their significance, the impacts on soil during the drilling operations phase are assessed as negative (-), of negligible intensity (IN=1), localised to the onshore port area (EX=1), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing port operations (SI=2), direct (EF=4), either periodic or occasional depending on the activity (PR=1-2), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Impacts on soil                                          |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

| Project Activities / Elements                            | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |            | Valued Receptor Assessment | Impact Significance |
| Logistics base chemicals management                      | -          | 1              | 1           | 4           | 1                | 1                  | 2            | 4           | 2                | 1             | 1                 | 21                    | Low        | Low                        | NEGLIGIBLE          |
| Logistics base waste management (including HW)           | -          | 1              | 1           | 4           | 1                | 1                  | 2            | 4           | 2                | 1             | 1                 | 21                    | Low        | Low                        | NEGLIGIBLE          |
| Logistics base drainage (discharge of rainwater run-off) | -          | 1              | 1           | 4           | 1                | 1                  | 2            | 4           | 1                | 1             | 1                 | 20                    | Negligible | Low                        | NEGLIGIBLE          |

#### 10.1.4.4.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, potential impacts on soil will be associated with removal of temporary facilities, dismantling of the logistics base, loading of equipment, waste contractor collections and final cleaning of the port area. These activities will be localised within the paved operational areas of the shore base in Igoumenitsa port.

No excavation, soil removal or permanent alteration of land surfaces is expected during demobilisation. Potential effects on soil would therefore be limited to accidental contamination, such as minor leaks or releases of fuels, oils, cleaning materials, liquid wastes or contaminated residues during dismantling, loading, waste handling and transfer operations. These risks will be managed through the continued application of spill prevention and response procedures, appropriate packaging and containment of wastes, inspection of containers prior to handling and collection, use of licensed waste contractors, and immediate clean-up of any accidental release. The likelihood of contaminants reaching underlying soils is minimized due to the implementation of these prevention and control measures.

Following demobilisation, all temporary facilities, equipment and waste materials will be removed from the shore base, and no residual source of soil impact will remain. Overall, impacts on soil during demobilisation and abandonment are expected to be negligible, localised, short-term and reversible.

In summary, with regard to their significance, the impacts expected on soil during the demobilisation and abandonment phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=1), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), non-synergistic (SI=1), direct (EF=4), discontinuous (PR=1), of immediate recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on soil                           |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.4.5 Seabed – sediment

##### 10.1.4.5.1.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, the principal impact pathways through which impacts to seabed sediment may occur are vessel presence and activity associated with vessel movements.

Due to the nature and scale of the implementation works, the drilling preparation and mobilisation phase of the project is not expected to cause any change in the seabed sediment characteristics of the study area. Mobilisation activities will be temporary and of short duration and therefore will not result in any measurable changes to sediment conditions, such as sediment characteristics including grain size distribution, effective thickness, nutrients, metals and hydrocarbon content.

In summary, with regard to their significance, the impacts expected on seabed / sediment characteristics during the mobilisation phase are assessed as negative (–), of negligible intensity (IN=1), within the local area (EX=2), occurring immediately during mobilisation activities (MO = 4), coincident with mobilisation activities (PE=1), short-term reversible (RV=1), non-synergistic (SI=1), direct (EF=4), discontinuous (PR=1), immediately restored (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **minor**.

#### 10.1.4.5.1.2 Exploration drilling operations phase

With regard to the exploration drilling operations phase, the principal impact pathways through which impacts to seabed sediment may occur are:

- Sediment removal,
- Introduction of a permanent structure on the seabed,
- Increase in sediment remobilisation and resuspension,
- Increase in sediment grain size,
- Increase in sediment effective thickness,
- Alterations to sediment chemical composition,
- Planned discharges,
- Drilling contingency activities.

The MODU's position will be maintained using its dynamic positioning (DP) system, which controls thrusters based on satellite navigation and acoustic reference systems. No anchors will be deployed, and no anchor handling or anchor-related seabed disturbance will occur. Seabed interaction associated with the temporary positioning transponders will be minor and spatially confined, and the transponders will be recovered following completion of operations.

Due to the nature and scale of the exploration works, the exploratory drilling operation phase of the project is likely to cause permanent changes to the seabed sediment characteristics of the study area. Operational activities, including cement discharges at seabed are expected to directly and immediately affect the local area at a discontinuous periodicity; resulting in a cumulative impact with a long-term reversibility and restoration.

The fine-grained bathyal marine sediment in the area is predominantly composed of “Mud” and “Silty clay” material. Survey results suggest a sediment compositional split of 85% fine-grained sediment, 15% as “Sand”, and an absence of “Gravel”. Resulting in increased suspended particulates, low energy depositional conditions, and generally low TOC concentrations. Hydrocarbon concentrations in surface sediments are generally low; with no evidence of hydrocarbon contamination or of measurable geochemical signatures associated with the underlying natural-gas accumulations. Any metal or metalloid concentrations were

reflective of concentrations reported from neighbouring Mediterranean offshore and coastal environments; suggesting the presence of natural geochemical variability rather than localized contamination (Annex 02, ESBS). Any changes to the sediments chemical composition as a result of external inputs, such as discharges, may alter the natural conditions of the sediment in the local area.

Increased suspended sediment concentrations via resuspension pose a threat to sediment composition and distribution, as disturbed fine sediments are more susceptible to longer periods of resuspension than that of coarse sediments with a larger grain size. Furthermore, slow current speeds of under 1 m/s at Project location water depths, may result in decreased dispersion and reversibility of impacts to disturbed sediment (see Annex 02, ESBS).

Operational activities, including MODU drilling with wellhead and casing installation, will directly and immediately impact sediment over a long-term duration. This activity will result in measurable long-term changes to sedimental conditions within the local area; such as disturbance of the seabed due to the removal of sediment from the drill site, re-distribution of the disturbed material due to discharges increasing suspended fine matter within the water column, and the addition of infrastructure to the seabed resulting in long-term alterations to the environment.

Based on the current design, the permanent physical footprint on the seabed associated with the exploration activity will be less than 1 m<sup>2</sup>. All temporary subsea infrastructure (including the BOP, marine riser, and transponders) will be removed; no production facilities, pipelines, control umbilicals, or surface installations will be installed. However, the retained well-head and cement plug will result in a permanent alteration of the physical seabed condition and the disturbance of the sediment composition at the drilling location.

Drilling and associated activities will result in the accumulation of drill cuttings and water-based drilling fluid discharges to the seabed (riserless drilling). Discharge of cuttings and fluids may lead to changes in sediment quality through sediment disturbance, redistribution and deposition of drilling-related materials onto the seabed. This may lead to minor localised physical and physio-chemical effects. These direct impacts are expected to be of high intensity with immediate effect over a short duration; with the potential for reversibility and restoration once the activity has ceased.

Cuttings dispersion modelling considered two seasonal periods: Season 1, from October to March, and Season 2, from April to September. These seasons were selected to represent the main metocean variability in the study area. Season 1 corresponds to the winter circulation regime, characterised by stronger and more variable winds and enhanced cyclonic activity, while Season 2 represents the summer circulation regime, with more stable atmospheric conditions, prevailing north-westerly winds over the Ionian Sea and lower average wind speeds.

The principal effect on the seabed is expected to be localised covering or smothering, where deposited material exceeds the 6.5 mm effective-thickness screening threshold<sup>62</sup>. This exceedance is predicted up to a maximum distance of 85.4 m from the well in both seasons, with a lower distance of 37.9 m under the 10-year Season 2 case.

Cuttings dispersion modelling also considers whether deposited material could increase the local median grain size. The baseline sediment at the discharge point is very fine, with a median grain size of approximately

---

<sup>62</sup> 5% of species affected, according to [https://www.sintef.no/globalassets/project/erms/reports/erms-report-no-9\\_threshold-non-toxic-stressors\\_tno.pdf](https://www.sintef.no/globalassets/project/erms/reports/erms-report-no-9_threshold-non-toxic-stressors_tno.pdf)

10 µm. A modelled risk above the 5% screening threshold occurs when the resulting median grain size exceeds approximately 116 µm. Grain-size change maximum predicted distances are 283 m in Season 1 and 397 m in Season 2.

These modelling results indicate that the morphological effect of drilling discharges will remain confined to the vicinity of the well location and will be driven mainly by physical sediment change rather than chemical toxicity. The footprint is therefore spatially limited and does not indicate a potential for any significant marine geomorphological change.

Hydrodynamic conditions at the drilling location will further contribute to the dispersion and redistribution of discharged material. Bottom currents and episodic marine processes may promote resuspension and reworking of fine sediments, preventing long-term consolidation of deposits. As a result, any seabed modification is expected to be localised, temporary to medium-term in nature and subject to natural sedimentary rebalancing processes.

The baseline sediment conditions showed negative oxidation reduction potential (ORP), which is indicative of the ability to break down contaminants and support biological processes; and is associated with cohesive fine-grained deposits, limited permeability and low oxygen penetration. Discharge modelling for both oxygen change and toxicity of chemicals suggests that discharge did not produce significant risk after 45 days after discharges cease. Given that the risk of oxygen depletion is low, this reduces the impact on associated sediment processes being affected, such as bioturbation.

The risk of smothering by cuttings will be greatest where thickness of cuttings is greatest. The threshold of thickness to be considered for smothering is 6.5mm (Singsaas et al., 2007). Studies suggest that generally increased sediment depth correlates positively with benthic mortality rates, increasing burial time with changes to sediment size differing from that of the species native sediment (Maurer, D., et al., 1981). The increase in grain size and effective thickness of the sediment, as a result of the cuttings discharge, has potential to disrupt natural processes like bioturbation; causing immediate, direct, and medium-term alterations to the environment in question. As stated within the discharge modelling report, the maximum thickness deposit on the seafloor at the release site after discharge was 56.9 mm in Season 1, and 53.9 mm in Season 2. After 10 years, a small reduction ranging between 55.4 mm in Season 1 and 52.3 mm in Season 2 is expected.

The increase in grain size, sediment thickness and increased distribution of fine particulate matter within the local area is likely to cause smothering on the seabed, impacting benthic habitats and organisms residing within the sediment. Sediment modelling indicates that exceedance of the effective-thickness screening threshold of 6.5 mm is highly localised around the well location. For both Season 1 and Season 2, the maximum predicted distance for exceedance is 85.4 m, indicating that potential smothering effects would be confined to the immediate drill-site area. In Season 2, under the 10-year high-current case, the predicted exceedance distance is lower, at 37.9 m, reflecting greater dispersion of deposited material. This result represents the conservative design-envelope assumptions applied in the modelling and is not necessarily representative of the expected operational discharge profile. Overall, the results indicate that sediment thickness impacts would be localised and limited in spatial extent, with the greatest potential for seabed smothering occurring close to the discharge point.

The discharge of water-based fluids and cuttings near sea surface (drilling with riser) is anticipated to have minimal impact on the seabed sediment within the project area, due to the surface-level discharge in water

depths of approximately 840m. Cuttings are discharged 12m below the water line, while drilling mud is recirculated. For the base-case well design, up to 453 tonnes of calcareous and carbonate-based cuttings and 1,158 tonnes of drilling fluids may be discharged on the well sections drilled with a riser in place. Impacts from this activity are expected to be indirect and temporary, with a short-term reversibility and restoration duration. It is anticipated that this material will be disperse naturally by currents throughout the water column, in relation to depth and lateral spread. This will reduce the accumulation of the discharged material within the activities area of influence, reducing the impact on the seabed sediments.

A median grain-size of approximately 75  $\mu\text{m}$  is deemed appropriate for almost all species, as this value corresponds to 0% of potentially affected species. Similarly, considering a 5% fraction of affected species, the median grain-size associated is approximately 48 $\mu\text{m}$  and 116 $\mu\text{m}$ , according to the cuttings dispersion modelling. Discharged cuttings typically range from very fine (20 $\mu\text{m}$ ) to very coarse (<10,000 $\mu\text{m}$ ) after removing the fluid. Although the very coarse grain size being discharged differs to the existing fine seabed sediment environment, the unlikely accumulation in one location minimises the impact on the seabed and reduces the potential sediment thickness. The change in sediment grain size as a result of sea surface discharges is unlikely to have a significantly detrimental impact on sedimentary processes.

Under normal operations, all cuttings associated with water-based mud (WBM) are expected to be free of hydrocarbon contamination and may be discharged in accordance with applicable regulatory requirements. The absence of hydrocarbons being released removes the potential for sediment contamination upon settlement. Furthermore, no chemicals proposed for use in drilling fluids or cementing operations are listed under Annex I (List of Substances the Use of Which Is Prohibited) of the Offshore Protocol.

During riserless surface casing operations, up to 64.6 m<sup>3</sup> of cement may be discharged directly onto the seabed. This would cause a direct, localised and permanent physical impact within the immediate drill-site footprint, mainly through increased sediment thickness, smothering and the formation of hardened cemented material on the seabed.

Cement slurry is mainly composed of cement powder and water, with selected additives such as retarders, accelerators and fluid-loss additives. These additives will be screened in accordance with UNEP/MAP offshore chemical requirements and the Operator's chemical management system, with preference given to low environmental-risk products.

The greatest impact is expected close to the well location, where cement deposition may exceed the 6.5 mm smothering threshold. In this area, the natural fine sediment surface may be replaced or covered by cemented material, altering sediment composition, grain-size characteristics and seabed microtopography. Localised changes to sediment pH and oxygen conditions may also occur following cement settlement and solidification, although chemical effects are expected to be limited by the use of screened, lower-risk additives.

A further 15 m<sup>3</sup> is estimated to be cement discharges from the MODU near sea surface from the tank wash out, following cleaning of the cementing equipment upon activity completions. With an addition discharge of up to 48m<sup>3</sup> of cement slurry to sea from the drillship in the event of an aborted cementing operation. This impact is expected to be immediate and indirect within the project area, leading to permanent and irreversible changes that are likely to require a long-term restoration duration. The impact from the surface discharges will be less intensive than seabed discharges, with the deposition being dispersed across a greater distance, as a result of the water column currents and deep water at the project location. Although

larger grain sizes than are typical of the baseline conditions will be released, the dispersal will reduce the accumulation and sediment thickness of these deposits on the seabed; the impact is expected to be reduced by rapid dilution and dispersion within the water column of the local area.

Discharge of macerated food waste from the MODU may cause a localised, indirect impact on seabed sediments through the addition of organic matter. For the 67-day drilling campaign, the MODU is estimated to discharge approximately 12,663 kg of food waste, equivalent to about 189 kg/day. As the MODU will remain stationary, discharges will occur from the same offshore location, approximately 12 m below the sea surface. Due to the deep water at Asopus-1, approximately 840 m, and the influence of surface and water-column currents, food waste is expected to disperse during settling and is not expected to accumulate in significant quantities at a single seabed location. Therefore, the potential effect on sediments is mainly limited to a minor and localised increase in organic input. Baseline data indicate low TOC concentrations, low ORP values and no evidence of significant organic or nutrient enrichment, consistent with an oligotrophic benthic environment (Annex 02, ESBS). Additional organic input from food waste could locally alter sediment nutrient conditions; however, the impact is expected to be temporary, short-term, reversible and limited to the Project area.

A further immediate impact on the seabed within the project area may occur during ROV operations, which may require wet parking of the ROV. This direct contact with the sediment will result in temporary sediment displacement, increased suspended sediment and subsequent deposition. This will be a short-term activity with potential for short-term reversibility and restoration of the seabed once the activity has concluded. The disturbed sediment will likely resettle in proximity to the ROV parking location and is unlikely to result in sediment winnowing or significant remobilisation and deposition of contaminated sediment. Furthermore, ROV activities will be conducted in accordance with the general obligations of the Barcelona Convention Offshore Protocol to prevent pollution and minimise impacts on the marine environment.

With regard to impacts from drilling contingency activities, re-spudding may increase the volume of discharged cuttings and cement, creating an additional or enlarged deposition footprint. Sidetracking may also increase cuttings generation, drilling fluid use and cementing requirements. An Emergency Disconnect Sequence could release riser contents at the seabed, resulting in localised deposition of drilling fluids and cuttings. Potential impacts include temporary turbidity, physical smothering of seabed sediments, minor alteration of surface sediment texture, and localised deposition of cement or drilling residues. These effects would be greatest during riserless drilling or seabed-level discharge scenarios. However, the effects would be spatially limited to the drilling area and would not affect sediment conditions at a regional scale.

In summary, with regard to their significance, impacts expected on seabed sediment characteristics during the operational exploration phase are assessed as negative (-), ranging from negligible to moderate (IN=1-4), within the project footprint to local (EX=1-2), immediate (MO=4), temporary or permanent throughout the drilling period, depending on the activity (PE=1-4), short-term to long-term reversible (RV=1-3), mostly synergistic (SI=1-2), direct (EF=4), irregular or continuous (PR=1-4), with immediate to long-term restoration (MC=1-4), and cumulative (AC=4). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

| Impacts on seabed - sediment                                                        |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |        |                            |                     |                                  |

#### 10.1.4.5.1.3 Demobilisation and abandonment phase

With regard to the demobilisation and abandonment phase, the principal impact pathways through which impacts to seabed sediment may occur are:

- Presence of a permanent structure on the seabed,
- Increase in sediment remobilisation and resuspension, grain size and effective thickness,
- Alterations to sediment chemical composition,
- Planned discharges,
- Vessel presence and activity associated with vessel movements.

As part of the demobilisation phase, cement plugs will be installed within the wellbore; any seabed effects will be limited to associated discharges and the retained wellhead. These impacts are expected to be short-lived and localised with immediate effect on the sediment.

Wellbore contents and fluids are to be displaced and circulated before being discharged to the sea under controlled conditions in accordance with approved procedures. A further discharge of 1,312 tonnes of drilling fluid may be conducted during the well plug and abandonment process. The settlement of these discharges on the seabed may cause localised changes to physical properties of the seabed, through deposition and potential changes in sediment grain size and thickness. Significant chemical changes are not anticipated, given that no chemicals proposed for use in drilling fluids or cementing operations are listed under Annex I of the Offshore Protocol.

Furthermore, discharges of cement contaminated seawater are expected to occur during circulation and surface handling operations on the MODU. The direct and immediate impacts of cement materials on sediment composition, both physically and chemically, are expected to be cumulative and long-lived within the local area; leading to long-term reversal and medium-term restoration potential, upon settlement. However, any discharges associated with surface handling would result in lower intensity than that of any direct discharges to the seabed, due to the deep-water depths giving opportunity for dispersion and dilution. Any seabed settlement will therefore also be dispersed over a wider geographic range.

The removal of temporary subsea infrastructure is considered to have a direct and immediate positive impact on seabed sediment within the local area. Upon completion of well plug and abandonment activities, temporary equipment installed for the drilling campaign will be disconnected, secured, and demobilised; followed by a post-operation ROV seabed survey to confirm seabed clearance and verify that no debris or residual equipment remains at the well site. The removal of subsea infrastructure will enable natural processes the potential to restore and reverse within the medium-term, without the risk of chemical leaching from these structures into the sediment. It also removes the potential for any temporary subsea infrastructure to externally influence sedimentation.

The demobilisation and abandonment phase will be subject to further ROV operations previously discussed in the exploration drilling operations phase, supporting a post operation surveys to verify seabed clearance from debris before the rig release. The impacts of this activity during the demobilisation phase of the works are anticipated to be of similar nature to that of the support during the operations phase. Direct contact with the seabed within the project area, if any, will cause temporary displacement of sediment, increased suspended sediment and subsequent deposition.

In summary, with regard to their significance, the negative (-) impacts expected on seabed sediment characteristics during the operational exploration phase are assessed as of negligible to moderate intensity (IN=1-4), within the project footprint to local area (EX=1-2), immediate (MO=4), temporary to long-lived (PE=1-3), short-term to long-term reversible (RV=1-3), non-synergistic or synergistic (SI=1-2), direct (EF=4), irregular or continuous (PR=1-4), with immediate to long-term restoration (MC=1-4), and mainly cumulative (AC=1-4). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

## 10.1.5 Impacts on the biotic environment

### 10.1.5.1 Terrestrial biotic environment

---

#### 10.1.5.1.1 Terrestrial habitats – vegetation

The proposed activities for the exploration well concern the marine environment. The onshore activities are limited to the port of Igoumenitsa for the storage, staging, and loading or unloading of equipment, materials, consumables, and wastes and Corfu International Airport (CFU) for the support of the offshore operation by routine aviation logistics for the personnel transportation, including helicopter operations. The locations of the onshore infrastructure do not involve any significant vegetation. No impacts on terrestrial habitats on vegetation are anticipated, as all project activities do not involve disturbance of terrestrial land or vegetation.

#### 10.1.5.1.2 Terrestrial fauna

Similar to the terrestrial vegetation, terrestrial fauna is not expected to be affected by the proposed project. As all project activities are restricted to the marine environment, port of Igoumenitsa and Corfu International airport, no direct, indirect, or cumulative impacts on terrestrial fauna are anticipated. Avifauna is addressed separately in section 10.1.5.3.

### 10.1.5.2 Marine biotic environment

---

#### 10.1.5.2.1 Benthic fauna

##### 10.1.5.2.1.1 Drilling preparation and mobilisation phase

The mobilisation of the MODU (Stena DrillMAX) to Block 2 via self-propulsion, together with associated support (Stephen Wallace Dick) and supply vessels (Swift Tide), has the potential to cause temporary disturbance to the benthic environment through:

- Vessel presence and activity associated with vessel movements
- Power generation.

Due to the nature and scale of the implementation works, direct impacts to the benthic habitats within the study area during the drilling preparation and mobilisation phase of the project are expected to be short-term and reversible. Mobilisation activities, including the mobilisation of the MODU to the well site and power generation, are temporary and of short duration. This activity will not result in any significant changes to the benthic habitat conditions; such as habitat characteristics including seabed sediment grain size distribution, demersal water quality, nutrients, metals and hydrocarbon content in sediments, or changes in the quality or composition of seabed species make up. The water depth at Asopus-1 is approximately 840m, and therefore limits surface-level contaminants interacting with the seabed and offers an extensive spatial range for dispersion within the water column. Additionally, due to the water depths in the Block 2 drilling area, the

MODU selected for the drilling will be dynamically positioned. Therefore, there will be no anchoring impacts associated with mobilisation of the rig.

In summary, with regard to their significance, the impacts expected on benthic fauna or habitat characteristics during the mobilisation phase are assessed as negative (-), of negligible intensity (IN=1), within the project area (EX=1), immediate (MO=4), coincident with mobilisation activities (PE=1), short-term reversible (RV=1), synergistic (SI=2), indirect (EF=1), discontinuous and irregular (PR=1), immediately restored (MC=1), and cumulative (AC=4). In terms of their overall significance, these impacts are assessed as negligible (Im=20), VR significance of medium, and impact significance as negligible. In summary, with regard to their significance, the impacts expected on benthic fauna or habitat characteristics during the mobilisation phase are assessed as negative (-), of negligible intensity (IN=1), within the project area (EX=1), immediate (MO=4), coincident with mobilisation activities (PE=1), short-term reversible (RV=1), synergistic (SI=2), indirect (EF=1), discontinuous and irregular (PR=1), immediately restored (MC=1), and cumulative (AC=4). In terms of their overall significance, these impacts are assessed as negligible (Im=20), VR significance of medium, and impact significance as negligible.

#### 10.1.5.2.1.2 Exploration drilling operations phase

With regard to the exploration drilling operations phase, the principal impact pathways through which impacts to benthic habitats may occur are:

- Sediment removal
- Introduction of a permanent structure on the seabed
- Increase in sediment remobilisation and resuspension
- Increase in sediment grain size
- Increase in sediment effective thickness
- Alterations to sediment and water column chemical composition
- Planned discharges
- Increase in underwater noise
- Increase in light pollution
- Vessel presence and activity associated with vessel movements.

The offshore EBS identified an overall infaunal community in the project areas that exhibited low values of abundance, species richness, and diversity; consistent with those typically recorded in Mediterranean bathyal environments. The macrobenthic communities are taxonomically poor, and the community structure is dominated by the phylum Annelida with a marked prevalence of the Sipunculid *Golfingia* sp.; which is a typical inhabitant of deep muddy sediments (LIGHTHOUSE, 2026[RN1.1]). The EBS did however record

deepwater coralligenous habitats in close proximity to the Asopus-1 well site. These were recorded at Station D4a and within a limited area on rocky substrate giving an isolated habitat of Mediterranean Upper Bathyal Rock (EUNIS (2022) code: ME15). The deepwater coral community identified at this location was characterized by the presence of corals attributable to *Antipathella subpinnata* or *Callogorgia verticillata* Annex 02, ESBS). These impact-receptor pathways are discussed below, with the drilling discharge modelling, taken into consideration (see section 6.9.1.1.1).

The ESBS did not identify any other sensitive seabed habitats (such as pockmarks or potential cold-gas-seeps) or sensitive species (such as coralligenous habitats and rodolith/maerl beds) in the immediate vicinity of the Asopus-1 wellsite with the exception of those observed at Station D4a (approximately 500m from the well site). However, it is noted that drilling will be within the South Adriatic Ionian Strait (Ecologically or Biologically Significant marine Area); which is designated for deepsea coral communities and deepsea sponge aggregations. This has not been deemed as a critical area in the immediate area of the drill site, due to the limited range of the deepsea coral habitats observed during the ESBS report (Annex 02).

During the exploratory drilling operation phase, direct disturbance to the seabed from MODU drilling operations, associated discharges (particularly riserless discharges of cuttings and associated drill fluids directly at the seabed), and sea surface discharges (both riser discharges of cleaned cuttings and routine operational discharges) all have capacity to impact the benthic community in the local vicinity of the Asopus-1 wellsite. These impacts can occur through smothering of the benthic community, and changes to both the physical and chemical sedimentary composition; due to the introduction of foreign substances (e.g. cement), as well as associated drill fluids, which could potentially disrupt respiratory surfaces. Although the macrobenthic community is considered to be taxonomically poor, with the exception of those observed at Station D4a during the offshore ESBS, the species which are present may be less tolerable to changes in environmental conditions given the relatively stable conditions at 840m below sea level.

Much of the existing benthic environment can be assigned to the Mediterranean Upper Bathyal Mud biocenosis (EUNIS code: ME65), characterised by fine-grained sediments and strongly limiting environmental conditions in terms of light availability, temperature, and organic matter supply. Furthermore, the biocenosis is characterized by the presence of carbonate oozes composed of skeletal remains of planktonic organisms such as coccolithophores, foraminifera, and pteropod molluscs.

Based on the current design, the permanent physical footprint on the seabed associated with the exploration activity is expected to be less than 1m<sup>2</sup> to retain the wellhead in place. The drilling activity, therefore, has a direct and potentially long-term impact on the benthic habitat at the location of the drilling, if infrastructure such as the well head remain in place. The direct disturbance will permanently remove the current benthic habitat and associated infauna residing within the seabed. In addition the wellhead structure will introduce a new hard substrate into an area of soft substrate, potentially increasing the potential for colonisation of invasive non-native species (INNS).

The temporary seabed disturbance during the drilling operation will result in the localised disturbance of seabed sediments and subsequent increases in SSC within the immediate vicinity of the well location. Sediment particles released into the water column are anticipated to disperse and settle progressively with increasing distance from the source. Whilst changes in the water quality and sediment quality as a result of drilling operations may have the potential to alter the benthic habitat and infaunal species. However,

adherence to MARPOL and the IMO Ballast Water Convention will help mitigate the potential impacts from INNS.

The associated discharge of cuttings may lead to changes in water quality, increases in suspended sediment, and smothering of the benthic environment. Discharged drilling fluid and cuttings will accumulate on the seafloor, leading to alterations in sediment grain size and could also result in alterations to the localised benthic community.

Metals in drilling fluids exhibit a very low bioavailability to marine animals (Neff et al., 1987), though there has been documented cases of bioaccumulation of barium sulphate, which is an inert, naturally occurring chemical. However, it is acknowledged that barium sulphate (Barite) will only be used as a contingency chemical during exploratory drilling. Where bioaccumulation has been documented, levels were not high enough to be harmful to species (Neff et al., 1987); therefore, it is unlikely that bioaccumulation effects would become significant. The expected main impact on the benthic environment is via smothering, owing to the overall low toxicity of most drilling fluids (NRC, 1983; Neff, 1987; Hinwood et al., 1994) as additives are screened through the operator's chemical management system using recognised offshore chemical screening schemes (e.g. PLONOR, OCNS, or equivalent).

Drilling discharge modelling suggested that grain-size change in sediments was identified as the primary contributor to overall risk. The significant risk extended up to 283m to the SW in Season 1 (October to March winter circulation – most frequent current scenario), and 396m to the SE in Season 2 (April to September summer circulation – high intensity currents scenario). After 10 years, this distance reduced to a maximum of 213m and 287m to the SW and SE, respectively. Both scenarios showed an impacted area of 27,500m<sup>2</sup>, but these assume a conservative scenario that all primary and contingent chemicals are used to the maximum concentrations.

Grain size change is of particular importance to the infaunal community, for which the current natural habitat consists of fine material; predominantly assigned to the “Mud” and “Silty clay” classes with an absence of “Gravel”. Deposits from the discharge may alter the structure of this habitat. This long-term increase in grain size is likely to result in unfavourable conditions for burrowing species within the deep muddy sediment; including the current community structure, which is dominated by the phylum Annelida and inhabited by Sipunculid *Golfingia* sp.. In addition, more sensitive isolated coral communities on rocky substrates will be of increased sensitivity to changes in sediment distribution and levels of introduced sedimentation as a result of drill cutting discharges.

The increased thickness of the sediments in these conservative scenarios, as a result of operational discharges, has the capacity to smother benthic species and the potential to reduce oxygen. However, discharge modelling for both oxygen change and toxicity of chemicals suggests that discharge did not produce significant risk after 45 days nor the 10-year modelling period. The modelling results also indicated a change in the effective thickness of the sediment, following the drilling discharges. The maximum thickness of deposit on the seafloor at the release site after discharge was 56.9mm in Season 1, and 53.9mm in Season 2. After 10 years, a small reduction ranging between 55.4mm in Season 1 and 52.3mm in Season 2 is expected.

Studies suggest that generally increased sediment depth correlates positively with benthic mortality rates, increasing burial time with changes to sediment size differing from that of the species native sediment (Maurer, D., et al., 1981). The increase in grain size and effective thickness of the sediment, as a result of

the cuttings discharge, has the potential to disrupt natural processes like bioturbation. The risk of smothering by cuttings will be greatest where thickness of cuttings is greatest. The threshold of thickness to be considered for smothering is 6.5mm (Singsass et al., 2007). This value is exceeded by the modelling predictions in both season 1 and 2. The conservative scenario modelling results show little decrease over the 10 year period and therefore the impacts from the change in sediment thickness are considered to be permanent.

This increase in sediment thickness will impact the benthic habitat within the immediate vicinity of the well site, which includes the infaunal community; the current benthic environment can be assigned to the Mediterranean Upper Bathyal Mud biocenosis (EUNIS code: ME65), characterized by fine-grained sediments and strongly limiting environmental conditions in terms of light availability, temperature, and organic matter supply. Furthermore, impacts will affect the limited rocky benthic habitats in the immediate vicinity of the well site dominated by deepwater coral species (Mediterranean Upper Bathyal Rock (EUNIS code: ME15). The increased sediment thickness will further reduce the ability of the organic matter supply to move through the sediment, as a direct result of the increased sediment thickness settling on top of the current finer material present.

The discharge of water based fluids and cuttings near sea surface during riser drilling is anticipated to have a localised impact on the benthic fauna or habitat, due to the surface-level discharge in water depths of approximately 840m. Cuttings are discharged 12m below the sea surface, while drilling mud is recirculated. For the base-case well design, up to 490 tonnes of calcareous and carbonate-based cuttings and 1,318 tonnes of associated drilling fluids may be discharged on the well sections drilled with a riser in place. Drilling discharge modelling suggested that grain-size change in sediments was identified as the primary contributor to overall screening-threshold exceedance. Under the conservative design-envelope assumptions applied in the modelling. The risk extended up to 283m to the SW in Season 1 (October to March winter circulation – most frequent current scenario), and 396m the SE in Season 2 (April to September summer circulation – high intensity currents scenario). After 10 years, this distance reduced to a maximum of 213m and 287m to the SW and SE, respectively. These results are not necessarily representative of the expected operational chemical-use and discharge profile.

It is anticipated that this material will be dispersed naturally by currents throughout the water column, with lower dispersion rates the further down the material travels and current speeds of under 1m/s. This will reduce the accumulation of the discharged material within the activities area of influence, reducing the impact on the benthic fauna or habitats. Under normal operations, all cuttings associated with water-based mud (WBM) are expected to be free of hydrocarbon contamination and may be discharged in accordance with applicable regulatory requirements.

A median grain-size of approximately 75µm is deemed an appropriate level for almost all benthic species, as this value corresponds to 0% of potentially affected species. Similarly, considering a 5% fraction of affected species, the median grain-size associated is approximately 48µm and 116µm. Discharged cuttings typically range from very fine (20µm) to very coarse (<10,000µm) after removing the fluid.

The change in sediment grain size, as a result of sea surface discharges of very coarse sediments, is likely to have a minor impact on the current benthic environment upon settlement. Although the discharged sediment differs to the existing substrate, it is unlikely to accumulate in one location due to the increased opportunity for dispersion within the water column; minimising the impact on the benthic environment. With

regards to contaminant releases, the absence of hydrocarbons being released (under normal operations), removes the potential for sediment contamination upon settlement which would prove harmful to the benthic ecosystem. Furthermore, no chemicals proposed for use in drilling fluids or cementing operations are listed under Annex I (List of Substances the Use of Which Is Prohibited) of the Offshore Protocol.

Drillship dynamic positioning (DP) transponders and remotely operated vessel (ROV) equipment will come into direct contact with the seabed during the operational phase, causing minor disturbance to the benthic habitat. This direct contact with the seabed habitat will result in temporary sediment displacement, increased suspended sediment, and subsequent deposition. This will be a short-term activity with potential for short-term reversibility and restoration of the seabed, once the activity has concluded. The disturbed sediment will likely resettle in proximity to the ROV wet-parking and transponder deployment locations, and is unlikely to result in sufficient levels of disturbance. Furthermore, these activities will be conducted in accordance with applicable AEPO conditions and with the general obligations of the Barcelona Convention Offshore Protocol to prevent pollution and minimise impacts on the marine environment.

During riserless surface casing operations, up to 64.6m<sup>3</sup> of cement will be discharged onto the seabed. The threshold of thickness to be considered for smothering is 6.5mm (Singsass et al., 2007), cement discharges are expected to exceed this thickness. Upon material settlement and solidification, localized changes may occur in oxygen and pH levels in the seabed sediment within the project footprint. These alterations will change the composition of the habitat and infaunal community in the local area. This discharge will directly impact the benthic habitat, resulting in continuous and irreversible alterations to the habitat, sediment composition and seabed landscape within the local area. The benthic habitat may change in composition as a result of the increase in grain size due to the introduction of cement material to the existing fine sediment environment, and an increase in sediment thickness causing smothering of seabed habitats including potentially higher sensitivity habitats (e.g. deepsea corals).

Discharges to the marine environment have the potential to affect benthic habitats and communities through temporary changes in water quality, increased turbidity and exposure to drilling related discharge. However, there is no direct impact pathway from pipe dope on the benthic environment as there are only minor traces when risers are in place. Benthic fauna may be exposed to water-column changes, including riser drilling discharges, cement discharges, drainage water, cooling water, ballast water and wastewater. Benthic fauna and habitats may additionally overlap with seabed-associated discharge plumes resulting from riser drilling discharges, pipe dope, blowout preventer discharges and cementing activities.

It is estimated that 15m<sup>3</sup> is to be discharged from the MODU at the sea surface, following cleaning of the cementing equipment upon activity completions, with additional discharges of up to 48m<sup>3</sup> of cement slurry to sea from the drillship in the event of an aborted cementing operation. The impact on the benthic environment from the surface discharges will be less intensive than seabed discharges, with the deposition being dispersed across a greater distance. Although larger grain sizes than are typical of the baseline conditions will be released, the impact on the benthic environment is expected to be reduced by rapid dilution and dispersion within the water column; reducing the accumulation of these deposits in a concentrated location on the seabed, with a medium-term reversibility.

Desalination unit discharges from MODU and the uplift and discharge of cooling water from MODU will take place during the operational phase. With regards to cooling water, there will be an estimated total discharge of 101,760m<sup>3</sup>/day based on all systems running and topside cooling system running all 3 pumps. There will

be an estimated daily brine discharge of 1,174m<sup>3</sup> (brine from water maker, condensate) and 238m<sup>3</sup> (brine from water maker, 2 RO systems). Desalination and cooling water discharges are unlikely to significantly affect benthic species as the discharge point will be within surface waters; with a discharge depth between 5-12m below sea surface, allowing for dispersion and dilution with limited potential for impact on the benthic habitat.

Other operational discharges, including discharges of sanitary waste, food waste and drainage water from the MODU and support or supply vessels are also anticipated to have minimal impacts on the benthic habitats; due to the discharges occurring at sea surface-level (maximum depth of 12m below surface). These discharges will then be subject to dilution and dispersion before any potential interaction with the seabed habitats and, therefore, any additional nutrients associated with discharged material will not have significant impact on the benthic infauna, habitat or associated sedimentary processes.

Discharge of ballast from MODU and support or supply vessels is not anticipated to have any significant impact on the benthic habitat. There may be a daily ballast discharge of 22m<sup>3</sup> during the operations (discharges at 1m below the surface). Under normal operations, ballast water is discharged only after treatment to meet the D2 performance standard for living organisms; in exceptional circumstances, sequential ballast water exchange to the D1 standard may be used as a contingency measure in approved offshore areas, in line with the vessel's Ballast Water Management Plan. Implementation of the approved Ballast Water Management Plan and adherence with MARPOL and the IMO Ballast Water Convention will contribute to mitigating any negative impacts on the benthic environment, following discharge; use of a certified Ballast Water Treatment System (BWTS) to meet the D-2 standard for ballast water discharges, with D-1 open-ocean exchange retained only as a contingency method where applicable and ensure all ballast operations recorded in the Ballast Water Record Book. Although there is potential for ballast water material to reach the benthic habitat following discharge, the contents is not considered to cause negative impacts to the seabed given the mitigations mentioned previously in this section.

In summary, with regard to their significance, the impacts expected on benthic fauna/habitat characteristics during the exploration drilling operations phase are primarily assessed as negative (-), with intensity ranges from negligible to high (IN=1-4), spatial extent from within the project site to regional/national (EX=1-4), occurring immediately during drilling activities (MO=4), coincident with drilling activities are permanent (PE=1), ranging from short-term reversible to irreversible (RV=1-4), with non-synergetic to synergistic interaction effects (SI=1-2), direct and indirect (EF=1-4), discontinuous and continuous in nature (PR=1-4), characterised by immediate to long-term restoration (MC=1-4), and non-cumulative to cumulative (AC=1-4). In terms of their overall significance, these impacts are assessed as negligible to moderate (Im=19-55), VR significance of medium to high, and impact significance as negligible to significant.

Following the implementation of prevention and mitigation measures described in **Chapter 11** of this ESIA, **residual impacts** are assessed as **minor**.

| Impacts on benthic fauna      |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |     |                            |                     |                                  |

#### 10.1.5.2.1.3 Demobilisation and abandonment phase

With regard to the demobilisation and abandonment phase, the principal impact pathways through which impacts to benthic habitats may occur are:

- Introduction of a permanent structure on the seabed
- Increase in sediment remobilisation and resuspension
- Increase in sediment grain size
- Increase in sediment effective thickness
- Alterations to sediment and water column chemical composition
- Planned discharges
- Vessel presence and activity associated with vessel movements.

Minor discharges of cement contaminated seawater may occur during cement plugging and abandonment activities, primarily during circulation and surface handling operations on the MODU. However, any discharges associated with surface handling would result in lower intensity than that of any direct discharges to the benthic habitats, due to the deep water depths giving opportunity for increased dispersion and dilution within the local area. Any impacts on the benthic habitat will therefore also be dispersed over a wider geographic range with a short-term recoverability duration. However, the persistence of these materials (e.g. cement) may remain in the benthic ecosystem upon settlement.

The removal of temporary subsea infrastructure is considered to have both a positive and negative impact on benthic fauna and habitats. Upon completion of well plug and abandonment activities, temporary equipment installed for the drilling campaign will be disconnected, secured, and demobilized, followed by a post-operation ROV seabed survey to verify seabed clearance and identify any Project-related debris or residual equipment requiring recovery.

The removal of any subsea infrastructure will enable natural processes to improve and restore within the long-term, without the risk of chemical leaching of any nature into the benthic ecosystem or disturbance to the benthic faunal communities. However, temporary infrastructure may provide habitat that could sustain

colonisation which could be used by benthic fauna; in addition, removal will result in resuspension of the seabed sediment and disturbance to the benthic habitat in the local area. Benthic communities may be deterred from inhabiting temporary infrastructure due to the relatively short project duration and the ongoing infrastructure deployment activities, the negative impact of the removal is reduced. Overall, the benthic fauna will be positively impacted, as this activity will allow conditions to return to near baseline conditions.

As part of the demobilisation phase, cement plugs will be installed within the wellbore; potential effects on the benthic ecosystem will arise from associated discharges within the local area. Wellbore contents and fluids may be displaced and circulated before being discharged to the sea, under controlled conditions in accordance with approved procedures; including weighted drilling mud, cement contaminated mud, water, barite, and cement polymers. Up to 1,312 tonnes of drilling fluid may be conducted during the well plug and abandonment process.

The settlement of these discharges and their constituents on the seabed will cause localised physical changes to the seabed by increasing the sediments grain size, causing increased suspended sediment and increased dispersion. Significant chemical changes are not anticipated, given that no chemicals proposed for use in drilling fluids or cementing operations are listed under Annex I (List of Substances the Use of Which Is Prohibited) of the Offshore Protocol. The nature of cement does however give rise to persistence in the benthic ecosystem, resulting in a medium-term reversibility and long-term restoration to the benthic habitats original natural state.

The demobilisation and abandonment phase will also be subject to a ROV post-operations seabed survey, to verify seabed clearance and identify any Project-related debris or residual equipment requiring recovery. The impacts of this activity is anticipated to be of similar nature to that of the support during the operations phase; direct contact with the seabed will cause temporary displacement of sediment, increased suspended sediment and subsequent deposition. This will be a short-term activity with very limited impact on the seabed if at all as the ROV operation acts more as an embedded mitigation to ensure the seabed is being left in an acceptable condition.

Settlement of resuspended sediment on the benthic substrate during wet landings will be localised, due to the low current speeds and larger grain size presence than before the demobilisation and abandonment phase. The use of an ROV will also introduce artificial noise and lighting; these influences may alter behaviour of the benthic fauna and result in short-term avoidance of the project site. However, ROVs are a common component of offshore inspections in the benthic environment and behavioural impacts are only expected when the ROV is in close proximity to benthic fauna. Additionally, ROV surveys have a short duration and its impacts will not expand outside the project area.

In summary, with regard to their significance, the impacts expected on benthic fauna and habitat characteristics during the demobilisation and abandonment phase are primarily assessed as negative (-), with intensity ranges from negligible to low (IN=1-2), spatial extent from within the project site to local area (EX=1-2), occurring immediately during demobilisation activities (MO=4), coincident with demobilisation activities ranges from brief to permanent (PE=1-4), ranging from short to medium-term reversible (RV=1-2), with non-synergetic to synergistic interaction effects (SI=1-2), direct (EF=4), discontinuous to continuous in nature ranges from (PR=1-4), characterised by immediate restoration to long-term restoration (MC=1-4), and non-cumulative to cumulative ranging from (AC=1-4). In terms of their overall significance, these impacts are

assessed as negligible to low (Im=19-34), VR significance of medium to high, and impact significance as minor.

However, there is one impact (the removal of temporary subsea infrastructure) that has been assessed as positive (+), with the intensity as low (IN=2), spatial extent as localised (EX=2), immediate occurrence (MO=4), short-term coincidence with demobilisation activities (PE=2), medium-term reversibility (RV=2), with moderate synergistic interaction effects (SI=2), direct (EF=4), is irregular or discontinuous in nature (PR=1), characterised by long-term restoration (MC=4) and cumulative (AC=4). In terms of the overall significance, this impact is assessed as low (Im=33), VR significance of high, and impact significance as minor.

## 10.1.5.2.2 Plankton

### 10.1.5.2.2.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, no significant impacts on plankton are expected. Offshore activities will be limited to the transit and positioning of the MODU and support vessels at the well location.

### 10.1.5.2.2.2 Exploration drilling operations phase

During the drilling operations phase, two types of impacts on phytoplankton and zooplankton can be potentially expected. Those are physical impacts and impacts from chemical toxicity (Mazlova et al., 2019). The most likely chemical impacts would stem from toxic effects from the release of drilling related chemicals and fluids (drilling cuttings and mud). Copper ion (Cu<sup>2+</sup>), which can be used as H<sub>2</sub>S scavenger in drilling and mud systems, is widely considered the most toxic metal for plankton, inhibiting photosynthesis by Cu-chlorophyll formation (Küpper et al., 1996; Küpper et al., 2002). Iron (III) chloride (FeCl<sub>3</sub>), which is widely used in offshore drilling for water treatment and fluid processing, causes phytoplankton and bacterioplankton to coagulate (which is also the reason for its use in the seawater desalination industry). However, in open-ocean marine systems it is also an important, limiting micronutrient promoting phytoplankton growth (Küpper et al., 2026). This applies e.g. for the central Pacific and the Southern Ocean,

but not for the Mediterranean which receives ample particulate iron input from aeolian (wind-borne) dust from North African and Middle Eastern desert regions (Küpper et al., 2026).

According to the Chemical Use Plan (see Annex 05) for the exploration drilling of Asopus-1 there will not be any use of the abovementioned compounds (Copper ions or iron (III) chloride). Potential chemical effects on plankton are therefore assessed based on the full inventory, environmental classification and discharge quantities of the chemicals proposed for use.

Drilling discharges (cuttings and mud) can also have physical impacts, by increasing turbidity / reducing water transparency (which is a common problem also where mining operations involve disposal of waste rocks and soil in nearshore waters; Thomas et al., 2003) and thus light exposure for phytoplankton (and consequently reducing primary productivity) as well as coagulation of plankton communities. Also, particles from drill cuttings and mud may clog the gills or digestive tract of zooplankton in the immediate area surrounding the discharge site.

Using culture studies, Mazlova et al. (2019) observed sublethal effects of drilling wastes on both the diatom *Phaeodactylum tricornutum* and water fleas (*Daphnia magna*) as representative organisms for phytoplankton and zooplankton, respectively. However, it is also clear that effects in the sea are likely local in close proximity to a drilling operation given the high concentrations required for lethal effects on *Daphnia* (> 1 g/l).

When it comes to seismic surveys there are no clear impacts on the plankton. There is still uncertainty about population-level and long-term ecosystem impacts. McCauley et al. (2017) suggested that the abundance of copepods and cladocerans can be reduced by approximately 50% at distances of 509–658 m from seismic air guns, where received sound levels reach 156 dB re 1  $\mu\text{Pa}^2\text{s}$  SEL and 183 dB re 1  $\mu\text{Pa}$  peak-to-peak. No significant reduction in abundance is detected at distances of 973–1,119 m, corresponding to sound levels of 153 dB re 1  $\mu\text{Pa}^2\text{s}$  SEL and 178 dB re 1  $\mu\text{Pa}$  peak-to-peak. Vereide et al. (2023). found limited mortality and no detectable behavioral or gene-expression changes in this copepod species. Impacts from Vertical Seismic Profile, if they occur, are likely to be localized and greatest near the seismic source.

Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

| Impacts on plankton                                                                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |                                  |

#### 10.1.5.2.2.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, no significant impacts on plankton are expected. Offshore activities will be limited to the removal of the temporary subsea structure and transit of the MODU and support vessels.

### 10.1.5.2.3 Marine fish fauna

#### 10.1.5.2.3.1 Drilling preparation and mobilisation phase

The mobilisation of the MODU (Stena DrillMAX) to Block 2 via self-propulsion, together with associated Platform Supply Vessels (PSV), has the potential to cause temporary disturbance to marine fish communities through: increased underwater noise and vessel presence and activity associated with vessel movements.

Additional indirect pathways exist through impact to prey availability, access to breeding and feeding grounds from increased disturbances of vessels, and underwater noise within the marine environment. Fish species occurring within the immediate project area comprise a highly diverse assemblage of at least 371 species, including 310 ray-finned fishes (*Actinopterygii*), 60 cartilaginous fishes (*Chondrichthyes*), and 1 lamprey (*Petromyzonti*), with the wider 100 km study area supporting approximately 410 species (see Section 2.4.4 and Annex 01 of the ESBS). This assemblage includes numerous species of conservation concern, particularly elasmobranchs, with a proportion of which are classified under IUCN Red List as Vulnerable (10), Endangered (10), or Critically Endangered (15) within the project site in the Mediterranean region (see Section 2.4.4 of the ESBS).

Additional vessel presence will cause spatial displacement to fish in close proximity; however, this will be greatest for species occurring nearer the vessel, while effects on deeper-water species are expected to be limited. Potential behavioural responses to vessel presence may include temporary avoidance of the area, changes in schooling behaviour, different swimming direction/patterns, movement to deeper waters and short-term interruptions to feeding activities. Conversely, fish may also aggregate around the vessels location and use the vessel as a shelter, which in turn can attract predators. This is mostly likely to occur when the vessel is stationary in port, travelling at very low speeds or once it arrives to the drilling site. If fish species do avoid the vessels' location, this is a short-term impact (duration the vessel is in the immediate area) and once the vessel departs, fish will return to the area in a short timeframe, reducing the overall severity of the impact.

Fish are known to detect and respond to a broad range of underwater sound frequencies, with responses varying depending on species-specific hearing capabilities, behavioural ecology, life stage, and environmental conditions (Popper and Hawkins, 2019). Behavioural responses to underwater noise typically include temporary avoidance, movement away from the sound source, altered swimming behaviour and short-term disruption to feeding or schooling activity (Popper and Hastings, 2009). Due to the limited understanding of hearing capabilities for many marine fish species, underwater noise assessments are commonly undertaken using functional hearing groups rather than individual species. These hearing groups are based on fish auditory sensitivity and physiological characteristics, particularly the presence and function of a swim bladder. Popper et al. (2014) and Popper and Hawkins (2019) developed a series of fish hearing groups and associated acoustic impact thresholds to assess the susceptibility of different fish types to underwater noise exposure. The fish species expected to occur within the project area have therefore been assigned to the functional hearing groups described below:

- Group 1 - Fish with no swim bladder: These species lack a swim bladder or other gas-filled chamber. They are generally less susceptible to barotrauma (tissue injury caused by a difference in pressure between a gas-filled space inside an organ and the surrounding tissues.). Hearing is primarily through detection of particle motion rather than sound pressure. This group includes species such as flatfish, sharks and rays. Large tuna species are also included in this group, notably the Atlantic bluefin tuna (*Thunnus thynnus*), Albacore (*T. alalunga*), Bigeye tuna (*T. obesus*) and Skipjack tuna (*Katsuwonus pelamis*). Very little data have been acquired on the responses of fish to particle motion.
- Group 2 - Fish with swim bladders that are not involved in hearing: These species possess a swim bladder, which can respond to sound pressure. However, the swim bladder is not connected to the inner ear, as a result, hearing is largely dependent on particle motion like Group 1. Species in this group are typically sensitive to a relatively narrow frequency range.

- Group 3 - Fish with swim bladders close to but not directly connected to the ear: These species can detect both particle motion and sound pressure. They are sensitive to a broader frequency range than Groups 1 and 2. Examples include members of the Gadidae, Anguillidae and Sciaenidae families.
- Group 4 - Fish where hearing involves the swim bladder: The swim bladder is connected, directly or indirectly, to the inner ear. These species are sensitive to both particle motion and sound pressure. They typically hear across a wide frequency range (up to several kHz) and exhibit greater hearing sensitivity than Groups 1-3. Examples include members of the Holocentridae, Sciaenidae and Clupeidae families, as well as the large group of otophysan fishes.
- Group 5 - Fish eggs and larvae: Available evidence suggests hearing abilities are broadly similar to those of the adult form of the species. Swim bladders may develop during larval stages, potentially increasing susceptibility to barotrauma. There remains limited information on the effects of underwater sound and vibration on fish eggs and larvae.

The acoustic impact of vessel non-impulsive noise on fish fauna during the mobilisation phase is spatially constrained and strongly governed by vessel transit speed. Acoustic propagation modelling under representative operational hydrodynamic conditions indicates that during the approximately 7-hour transit of a platform supply vessel from the Port of Igoumenitsa to Block 2 at an open-water maximum speed of up to 14 knots, an individual animal experiences a brief pass-by exposure (0.5 to 1 hour). The threshold for low – level behavioural disturbance for fish (150 dBrms re 1  $\mu$ Pa) is predicted to reach a distance of 91 m. Upon arrival at the project site or at the port of Igoumenitsa, as the vessel is assumed to reduce speed (4 knots) for manoeuvring, this behavioural response zone reduces to 31 m.

Ambient baseline underwater noise levels within the region are typical of coastal and offshore environments subjected to anthropogenic shipping activity, with levels characteristically estimated between 100 and 120 dBrms re 1  $\mu$ Pa. The temporary increase in noise associated with project vessels is therefore expected to represent only a minor addition to the existing acoustic environment. Given the offshore location of the project, the mobility of affected species, and the extensive availability of suitable habitat throughout the region, deep-water fish and elasmobranch populations are not expected to experience significant or long-term impacts because of vessel-related underwater noise.

Impact pathways from vessel presence and underwater noise, indirect impact pathways may occur through changes in prey availability. As discussed, fish species may either avoid the area in response to disturbance or aggregate around vessels. These behavioural changes could result in temporary alterations in the distribution and availability of prey resources for predators. These effects are expected to be localised, short-term and reversible following the termination of mobilisation.

Overall, the impacts on fish from the marine support vessels during mobilisation are assessed as negative. Due to the fact that the vessels are constantly moving, any individual fish will only experience the noise briefly as the ship passes by (for less than an hour). Because of this short duration and small footprint, both the direct physical disturbance and noise effects are considered minor.

In summary, with regard to their significance, the impacts on fish fauna during the mobilisation phase are assessed as negative ( $S = -1$ ), with negligible intensity ( $IN = 1$ ), localised spatial extent / within the project site ( $EX = 1$ ), occurring immediately during mobilisation activities ( $MO = 4$ ), coincident with the mobilisation period/temporary ( $PE = 1$ ), short-term and fully reversible ( $RV = 1$ ), non-synergistic ( $SI = 1$ ), with direct effect ( $EF = 4$ ), discontinuous in nature ( $PR = 1$ ), characterised by immediate recovery potential ( $MC = 1$ ), and non-

cumulative (AC = 1). The calculated Impact Magnitude is therefore negligible (Im = 19). Taking into account the High Valued Receptor assessment for marine fauna, the overall impact significance is assessed as **minor**. A breakdown of impact significance by activity is provided in the table below.

| Impacts on fish fauna                                                             |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.5.2.3.2 Exploration drilling operations phase

With regard to the exploration drilling and other activities in the operations phase, the principal impact pathways through which impacts to marine fish communities may occur are underwater noise, spatial disturbance, planned discharges and artificial lighting.

Additional indirect pathways exist through impact to prey availability, access to breeding/feeding grounds and presence from discharges within the marine environment.

Firstly, underwater noise will be generated by non-impulsive MODU drilling activities and VSP operations (impulsive), as well as from power generation (noise from thrusters, machinery vibration and hydrodynamic flow noise) from the MODU and supply vessel activities. Potential impacts in fish species may include temporary avoidance of the area, changes in schooling behaviour, masking of biologically important sounds, disruption of feeding activities, altered swimming patterns, and increased energetic expenditure. Species possessing swim bladders that are connected to the auditory system (Groups 3 and 4) are highly sensitive to sound pressure, whereas cartilaginous fishes (Group 1), which lack swim bladders, are generally more sensitive to particle motion components of sound (Chapuis *et al.*, 2019).

Underwater noise modelling for the proposed impulsive noise VSP activities indicated that single-strike mortality and physical injury thresholds for all fish hearing groups were confined to within 125 m of the source. While each VSP operation is allocated a 12-hour survey window for tool deployment and testing, the active airgun discharge is limited to approximately 130 shots per well section, at 15-second firing intervals. This results in an active firing duration of approximately 97.5 minutes (1.63 hours) per section, with a contingency envelope evaluated up to 2.0 hours. Assessment using SEL-based criteria indicates that impact distances increase with exposure duration. During a 2-hour operational periods, mortality thresholds for sensitive fish (Groups 3/4) extended to 259 m (for 1 h), and 282 m (for 2 h), while recoverable injury thresholds extended to 285 m (for 1 h), and 422 m (for 2 h). For fish eggs and larvae (Group 5), mortality

ranges were predicted at 147 m (1 h), and 259 m (2 h). Overall, Fish Group 1 exhibited the smallest physical impact ranges, with mortality and recoverable injury remaining confined to 123 m for all exposure durations up to 2 hours. The low –level behaviour (150 dB) for all fish groups was predicted at 16.3 km. The Temporary Threshold Shifts for fish groups 3/4 and 1 the TTS was estimated at 1.7 km (for 0.5 h) up to 8.9 km (for 2 h).

These theoretical distances utilize a conservative mathematical approach by assuming that mobile fish remain at a single stationary coordinate for the entire duration of sound exposure. Because fish may move away from the immediate area upon sound onset and during the planned 20-to-30-minute soft-start procedure, the assumption of a stationary receptor accumulating sound energy over prolonged periods is rendered biologically not applicable. Furthermore, as noted in the scientific literature (Hawkins and Popper, 2017), a short-lasting startle response or temporary displacement does not equate to injury and is unlikely to affect key life functions or result in population-level changes to vital rates. Finally, given that the non-impulsive noise from drilling is some 25 dB lower than the noise arising from drillship operations during drilling activity, the contribution from drilling into the seabed is deemed negligible (the maximum distance for mortality and low-level behavioural effects is considered 31 m).

The hearing sensitivity of many Mediterranean fish species remains poorly understood and is therefore inferred from related species whose auditory capabilities have been studied. Of relevance and a species which auditory capabilities are known is the European hake (*Merluccius merluccius*), a commercially important demersal species that is classified as Vulnerable within the Mediterranean (IUCN, 2026). The species can occur at depths exceeding 370 m, overlapping with habitats present within the project area, and is considered to have medium hearing sensitivity. Other demersal fish assemblage's characteristic of the Eastern Ionian Sea, for example the blackbelly rosefish (*Helicolenus dactylopterus*), may exhibit localised behavioural avoidance of the project area during VSP operations. Similarly, deep-water elasmobranch species known to occur within the region, including species like the blackmouth catshark (*Galeus melastomus*), may demonstrate temporary movement away from noise-generating activities. Given the relatively large home ranges of many of these species and the extensive availability of suitable habitat within the wider region, any displacement is expected to be localised and temporary.

As identified in Section **Error! Reference source not found.**, vessel noise may also contribute to fish disturbance, particularly where cumulative underwater noise effects arise through the simultaneous operation of VSP operations, vessel movements and DP activities. Spatial overlap between these individual zones of influence may increase the likelihood of behavioural responses in fish species occurring within the immediate vicinity of operations. However, most species present within the project area are highly mobile and capable of avoiding localised disturbance sources.

Additionally, no significant impact pathway associated with vessel spatial presence is anticipated for fish species during operations, as most fish possess sufficient mobility to avoid vessels and operational infrastructure. In some cases, fish may aggregate around the stationary vessels and use the vessel as a shelter. However, any effects from vessel presence are expected to remain localised and temporary.

.Discharges to the marine environment have the potential to affect fish communities through temporary changes in water quality, increased turbidity, localised sediment deposition, and exposure to drilling related discharge. Drilling fluid will combine seawater, water-based mud and high-viscosity gel sweeps, with additions of xanthan gum and minor concentrations of soda ash. During the riserless drilling sections,

discharges will also include claystone and calcareous cuttings. The high-viscosity sweeps contain water-based additives including salts and water-soluble polymers, as well as contingency weighting and viscosifying materials. All chemical additives will be screened in accordance with recognised offshore chemical screening schemes.

Fish species may be exposed to water-column changes, including riser drilling discharges, cement discharges, drainage water, cooling water, ballast water and wastewater. Demersal and benthopelagic species may additionally overlap with seabed-associated discharge plumes resulting from riserless and riser drilling discharges, blowout preventer discharges and cementing activities

Drill cuttings dispersion modelling concluded that suspended material may be transported away from the discharge location under the influence of prevailing currents, with the plume extent varying according to seasonal oceanographic conditions. For the physical presence of suspended drill cuttings in the water column, a Predicted No Effect Concentration (PNEC) of 100,000 ppb (equivalent to 100 mg/L) has been applied as a screening threshold within the ERMS/DREAM risk-assessment framework. Elevated concentrations of discharged elements and compounds (such as calcium carbonate) are predicted to be localised and temporary, with environmental risk diminishing rapidly following termination of discharge activities due to dispersion and dilution processes within the open marine environment (see Section **Error! Reference source not found.**). Fish species occurring within discharge zones may temporarily avoid affected areas where elevated suspended solids reduce visibility or interfere with feeding behaviour. Small pelagic species may alter local schooling distributions, whilst demersal species could exhibit short-term avoidance of areas where sedimentation occurs.

Indirect impacts may also occur during discharge events through changes to prey availability. Reductions in water quality, increased turbidity, or localised effects on planktonic and benthic prey communities may temporarily alter feeding opportunities for fish species. Nevertheless, the offshore nature of the project area, combined with the temporary duration of discharges and rapid dilution characteristics of the receiving environment, indicates that impacts are likely to be limited to localised and short-term behavioural responses.

A specific consideration is justified for elasmobranch species of conservation concern, including those classified as Vulnerable, Endangered, or Critically Endangered under the Mediterranean IUCN Red List assessment. These species exhibit inherently low population growth rates, slow maturation, and low fecundity. With respect to shellfish receptors, deep-water cephalopods and crustaceans may be present within the wider Ionian Sea region. While octopus' species are typically associated with shallower shelf habitats and are therefore unlikely to occur in significant abundance within the project area, several oceanic and deep-water squid species are known from the Mediterranean Sea, including the European flying squid (*Todarodes sagittatus*), reverse jewel squid (*Histioteuthis reversa*), and umbrella squid (*Todaropsis eblanae*) (Bello et al., 1997; Palomba et al., 2021). These species are important components of pelagic and deep-water food webs and may serve as prey for fish, marine mammals and other higher trophic-level predators (Battaglia et al., 2011; Palomba et al., 2021). Deep-water crustaceans may also occur within the vicinity of the project area, including the giant red shrimp (*Aristaeomorpha foliacea*), blue and red shrimp (*Aristeus antennatus*), and deep-water rose shrimp (*Parapenaeus longirostris*), which are known to inhabit slope and bathyal environments throughout the Mediterranean (Cau et al., 2002; FAO, 2025). Consequently, any impacts on threatened elasmobranchs are expected to be short-term and localised due to their high mobility, wide-ranging distributions and the localised and short-term nature of project discharges, significant effects

on these elasmobranch and shellfish species or their populations are not expected. Any discharged material would be rapidly diluted and dispersed within the receiving environment, limiting the potential for population-level effects or sustained habitat alteration.

Finally, artificial lighting associated with the MODU and vessel may induce localised behavioural effects in some fish species through attraction or avoidance responses. Pelagic fish are known to aggregate around offshore structures (especially illuminated), potentially altering predator-prey interactions in the immediate vicinity of the MODU. However, such effects are expected to be spatially restricted and temporary. Given the short duration of the drilling campaign (expected duration of 67 days), the mobility of fish populations, and the extensive availability of similar habitat throughout the wider Ionian Sea, significant effects on the integrity of fish populations are not expected.

In summary, with regard to their significance, impacts expected on fish fauna during the operational exploration drilling phase are assessed as negative (-), ranging from negligible to moderate in magnitude (IN=1–4), occurring within the project footprint to the local area (EX=1–2), immediate or short-term (MO=2–4), temporary throughout the drilling period (PE=1–2), largely reversible to short-term reversible (RV=1–4), with limited to synergistic interactions depending on the activity (SI=1–2), direct or indirect in nature (EF=1–4), irregular to continuous (PR=1–4), with immediate to medium-term recovery (MC=1–3), and generally non-cumulative to cumulative (AC=1–4). Overall, most impacts are assessed as Minor, with **moderate** significance identified for activities associated with seabed and near-surface discharges of water-based drilling fluids and cuttings, cement discharges, vertical seismic profiling (VSP), support vessel movements causing direct spatial disturbance, and lighting from the MODU. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, all residual impacts are assessed as **minor**. Please refer to the table below for the detailed impact quantification by activity for the exploration drilling operational phase.

| Impacts on fish fauna                                                                         |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |                                  |

#### 10.1.5.2.3.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, the activities of MODU circulation and surface handling operations, cement plug installation and abandonment, and post-operation seabed survey using a remotely operated vehicle (ROV) have the potential to cause temporary disturbance to marine fish communities through increased underwater noise and the presence and operation of vessels and subsea equipment within the project area.

As discussed in Section **Error! Reference source not found.** and **Error! Reference source not found.**, exposure to underwater noise may result in spatial displacement of fish fauna and cause temporary avoidance behaviour. However, within the project site, species present are inherently mobile and will avoid the area when disturbance is elevated. Comparatively to the drilling phase, activities associated with the demobilisation and abandonment phase will be shorter, reducing the possibility for prolonged impacts. Underwater noise impacts associated with these activities are expected to be temporary and localised within the project site, with recovery expected following activity completion.

The use of a ROV will introduce artificial noise and lighting which is unusual for the deep-sea environment. These influences may alter behaviour of the fish fauna and result in short-term avoidance of the project site. However, ROVs are a common component of offshore inspection in the deep-sea environment and behavioural impacts are only expected when the ROV is in close proximity to fish fauna. Additionally, ROV surveys have a short duration, and its impacts will not expand outside the project area.

The removal of temporary subsea infrastructure (including the BOP, marine riser, and transponders) is expected to provide a mixed (negative/positive) impact the restoration of the seabed and associated habitats and communities. The physical removal of the infrastructure may result in minimal disturbance to the seabed including resuspending sediment; however, this is not expected to impact fish fauna due to its short duration. Temporary infrastructure may provide habitat that could sustain colonisation which could be used by fish fauna, although the seabed in which the infrastructure was directly interacting with wont return to its previous natural state. Due to the relatively short project duration (expected 67 days), a singular well and the association of infrastructure deployment with ongoing operational activities that may deter colonisation of fish communities, the negative impact of the removal is reduced. Overall, the physical removal process constitutes a minor, short-term disturbance. Conditions will return toward baseline, and fish fauna be expected to resume their normal distribution within the project area.

Negligible effects on fish fauna are expected during the cement plug installation with impacts being contained within the localised well area. Discharges associated with these activities may temporarily impact the water quality of the surrounding area, which may directly impact fish physiology in addition to indirectly affecting prey availability. This impact should be minimal and temporary due to the dispersal of discharged materials. Any predicted impacts are expected to be short-term and reversible, with recovery expected following completion of activities.

Following completion of demobilisation and abandonment activities, all impacts are expected to reduce, and conditions will return towards baseline conditions.

In summary, with regard to their significance, impacts expected on fish fauna during the well abandonment phase are assessed as predominantly negative (-), with the removal of temporary subsea infrastructure resulting in both beneficial and adverse effects (+/-). The impacts are of negligible magnitude (IN=1), confined to the project footprint (EX=1), occurring immediately or in the short term (MO=3-4), temporary (PE=1), readily reversible (RV=1), non-synergistic (SI=1), direct or indirect depending on the activity (EF=1-4), irregular (PR=1), with immediate recovery (MC=1), and non-cumulative (AC=1). Considering the high sensitivity of the valued receptor, all impacts are assessed as **minor** in significance. Please refer to the table below for the detailed impact quantification by activity for the well abandonment phase.

## 10.1.5.2.4 Marine mammals

### 10.1.5.2.4.1 Drilling preparation and mobilisation phase

The drilling preparation and mobilisation phase has the potential to induce impacts to marine mammals through the following principal pathways underwater noise, physical presence and associated spatial disturbance/elevated collision risk and indirect impacts through changes in prey availability.

The mobilisation of the MODU (*Stena DrillMAX*) via self-propulsion to Block 2 and any associated support / supply vessels has the potential to induce temporary spatial disturbance to marine mammals, eliciting behavioural disturbance. During transit, both coastal and offshore species may be impacted. The MODU will transit through the Mediterranean to the Asopus-1 location. It is assumed that the supply vessel transit will occur from Port of Igoumenitsa, notably through the Ionian Archipelago Important Marine Mammal Areas (IMMA) and South Adriatic Ionian Strait Ecologically or Biologically Significant Area (EBSA). Such behavioural disturbance may arise in the way of evasive manoeuvres (i.e., altering diving behaviour or swimming direction). The degree of response is species dependent, with avoidance behaviours of small-toothed cetaceans illustrated within 0.5 to 1.5 km of vessels (Richardson et al., 1995).

Neutral or positive reactions (i.e., attraction) has also been documented for a number of dolphin species (e.g., striped dolphin [*Stenella coeruleoalba*]) (Shane et al., 1986). Disturbance is of most concern to larger marine mammal species, including toothed and baleen whales (e.g., fin [*Balaenoptera physalus*] and sperm

[*Physeter macrocephalus*] whale). For this larger species collision is also a risk; though collisions with smaller species may also occur (van Waerebeek et al., 2007). Collisions are known to cause direct injury and/or mortality to marine mammals. Vessel strikes are identified as one of the primary anthropogenic threat to larger marine mammals (Wang et al., 2025). Larger tanker/cargo vessels are the most common vessels where collisions have been documented, likely attributed to vessel size and low manoeuvrability (Schoeman et al., 2020).

Vessel speed is one of the most significant factors in determining and subsequently reducing collision risk. Speeds of more than 14 knots present the greatest risks to marine mammals (IWC, 2011), and as a result slow vessel speeds should be committed to where practicable. However, it is noted that overall the drilling preparation and mobilisation phase is temporary and short in duration (approx. 15 d). A single MODU is not expected to significantly increase spatial disturbance to marine mammals when considered in the context of pre-existing vessel traffic within the Ionian Sea, where well defined shipping corridors already exist, though due to the sensitivity of receptors a precautionary approach will be taken with regard to the impact assessment. Collision hotspots are often considered to be greatest within coastal waters, but also Exclusive Economic Zones (EEZ) when considered in tandem with high vessel presence (Wang et al., 2025). When stationary, the MODU is not expected to induce significant spatial disturbance, with offshore species (e.g., Cuvier's beaked whale [*Ziphius cavirostris*]) considered to be of most relevance to the proposed drill locations.

Vessel noise (including DP) associated with support / supply vessels and the MODU further has potential to induce disturbance to marine mammals. Underwater noise modelling has been undertaken with regard to vessel noise, alongside other noisy activities. Marine mammals are split into functional hearing groups (low frequency [fin whale], high frequency [bottlenose dolphin, *Tursiops truncatus*], very high frequency [harbour porpoise, *Phocoena phocoena*] and phocid carnivores [Mediterranean monk seal, *Monachus monachus*]) based on their sensitivity to underwater sound, notably all groups have been considered as potentially present within the assessment area, where relevant. It is however noted that very high frequency cetaceans, such as harbour porpoise are noted as being rare in the Ionian Sea and so are unlikely to be impacted by noisy activities within the Block. In addition, noting the Block 2 location it is further unlikely that coastal species (i.e., Mediterranean monk seal and short-beaked common dolphin [*Delphinus delphis*]) will overlap directly with drilling activities, however individuals may intersect with zones of influence associated with underwater noise impacts. Please refer to Section 6.12.3.4 for detailed outline of individual species sensitivity to underwater sound.

Underwater acoustic modelling under representative operational hydrodynamic conditions indicates that during the transit of project vessels from the Port of Igoumenitsa to Block 2 (~130 km) at an open-water speed of 14 knots (an approximately 7-hour transit for the supply vessels), an individual animal experiences a brief pass-by exposure (0.5 to 1.0 hour). The Level B Harassment (threshold for behavioural disturbance applied in the underwater noise assessment) for all marine mammals was reached at a maximum distance of 19.7 km for the drillship, Stena DrillMAX, and 7.7 km for the platform supply vessel. These distances dropped to 153 m and 61 m, respectively, when vessel speeds were reduced from 14 knots down to 4 knots (speed assumed for manoeuvring). Low frequency cetaceans were deemed most sensitive (Sound Exposure Level [SEL]); threshold values representing an onset of auditory injury (PTS) were noted as maximum distances of 91 m for the Stena DrillMAX and 30 m for a PSV, while Temporary Threshold Shift (TTS) extended to distances of 596 m and 213 m, respectively (for a 0.5 to 1.0-hour pass-by exposure).

While the threshold for continuous-noise behavioural disturbance (120 dBrms) during 14-knot transit theoretically extends to 19.7 km, this represents a conservative screening result. The acoustic model relies on theoretical static screening, mathematically assuming an animal remains fixed at a single stationary coordinate for the entire duration of the exposure highly mobile marine fauna actively swim away from approaching sound sources, drastically reducing their accumulated exposure.

Furthermore, the Ionian Sea is already subject to intensive maritime uses and commercial shipping, which elevates the baseline ambient sound levels to approximately  $110 \pm 6$  dB re 1  $\mu$ Pa. Because the 120 dBrms screening threshold is highly conservative and falls within the range of this existing commercial shipping noise, the vessels transit is unlikely to cause biologically significant behavioural disruption before blending into the existing marine soundscape.

While auditory injury (PTS) theoretically could occur in the immediate vicinity of the vessels, the likelihood of such an event is considered extremely remote because the physical injury zone is exceptionally small (strictly confined to 30 m and 91 m). To mitigate these risks, the Project implements strict operational controls during transit; Project vessels will adhere to established transit routes and operate at speeds not exceeding 14 knots (reducing to 4 knots for site manoeuvring). Vessels will maintain a safe distance from any observed marine mammal, avoid approaching head-on, and steer behind their path. Through these embedded measures, and because individuals are expected to actively avoid the immediate sound source, the likelihood of auditory injury is expected to remain low, and individuals are expected to recover from any temporary behavioural disturbance following the vessel pass-by.

Any indirect impacts consequent of changes in prey availability is not foreseen to significantly impact marine mammals in the vicinity of the project. Marine mammals forage over large areas, with the Block area unlikely to represent a key foraging area for individuals. In addition, species are commonly generalist foragers with a number of prey options, should one be hindered consequent of project implementation. There is considered to be sufficient additional habitat available in the Ionian Sea and wider Mediterranean.

Vessels may transit through the Ionian Archipelago IMMA occurs, due to the IMMA being designated for the critically endangered Mediterranean monk seal, alongside other marine mammal species (short-beaked common dolphin). The South Adriatic Ionian Strait EBSA has also been considered as part of this impact assessment, due to its importance as key habitats for multiple species of marine mammals, notably Cuvier's beaked whale. However, as the site is not specifically designated for marine mammals and rather noted for its supporting habitats, it has not been considered a critical habitat as with the IMMA, however mitigation measures as identified with this report will be applied to both sites where overlap occurs. Further Natura 2000 sites designated for bottlenose dolphin are located in proximity to transit routes of support / supply vessels (e.g., Amvrakikos Kolpos, Delta Lourou Kai Arachthou (Petra, Mytikas, Evryteri Periochi, Kato Pous Arachthou, Kampi Filippiadas [GR2110001] and Esoteriko Archipelagos Ioniou (Meganisi, Arkoudi, Atokos, Vromonas [GR2220003]), as a result individuals from these sites may overlap with transit activities, however significant impacts to the integrity of such sites is not envisaged. It is acknowledged that the overall drilling programme is limited in duration (90 days) and that vessels and MODU will adhere to dedicated transit routes. Vessel speeds may be reduced as much as reasonably practicable when transiting through the IMMA and the EBSA site. All relevant international best practice and legal frameworks are expected to be adhered to.

In summary, with regard to their significance, impacts expected on marine mammals during the drilling preparation and mobilisation phase are assessed as negative (-) for all activities. The impacts are characterised by negligible impact magnitude (IN=1), confined to the project footprint (EX=1), occurring immediately (MO=4), temporary (PE=1), readily reversible (RV=1), with limited synergistic effects (SI=2), direct or indirect depending on the impact pathway (EF=4), irregular (PR=1), with immediate recovery (MC=1), and non-cumulative (AC=1). Considering the high sensitivity of the valued receptor, all identified impacts are assessed as **minor** in significance. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are expected to remain **minor**. Please refer to the table below for the detailed impact quantification by activity for the drilling preparation and mobilisation phase.

| Impacts on marine mammals                                                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.5.2.4.2 Exploration drilling operations phase

The exploration drilling and operations phase has the potential to induce impacts to marine mammals through the following principal pathways: underwater noise, physical presence and associated spatial disturbance/elevated collision risk, discharges and subsequent impacts through changes in water quality, toxicity and bioaccumulation, artificial lighting and potential attraction/disturbance and indirect impacts through changes in prey availability.

With regard to the exploration drilling and operations phase, underwater noise and spatial disturbance is the greatest concern for marine mammals, though additional pathways may exist from discharges into the marine environment.

The physical presence of the MODU and transit of vessels is not envisaged to induce significant spatial disturbance over the course of the exploration drilling operations phase. This is attributed to pre-existing vessel traffic within the Ionian Sea, alongside a degree of habituation of individuals to presence over the course of this phase.

Elevations in underwater noise will arise from MODU drilling activities, MODU operation, support / supply vessel operations (including DP) and VSP activities during this phase. Impacts may arise in the form of

behavioural disturbance (i.e., masking) or direct injury. Underwater noise modelling (see Section 6.12.3.4) has also been undertaken for the VSP and drilling activities, alongside noise generated from vessel movements. Please refer to Section 6.12.3.4 and the ESBS for a detailed outline of individual species sensitivity to underwater sound. Low frequency cetaceans were overall concluded to be the most sensitive to the underwater noise sound sources due to the frequency of sound emitted.

While each VSP operation is allocated a 12-hour survey window for tool deployment and testing, the active airgun discharge is limited to approximately 130 shots per well section, at 15-second firing intervals. This results in an active firing duration of approximately 97.5 minutes (1.63 hours) per section, with a contingency envelope evaluated up to 2.0 hours. Assessment using SEL-based criteria indicates that impact distances increase with exposure duration. During realistic 2-hour operational periods, Level B Harassment was predicted at 2.6 km for all marine mammals. The threshold for Temporary Threshold Shift (TTS) was predicted to reach 13.9 km (0.5 h), 18.4 km (1 h), and 23.3 (2 h) for Low Frequency Cetaceans. Respectively, the TTS (178 dB SEL) for High-Frequency Cetaceans was predicted to reach 123 m (0.5h, 1h, 2h), whilst the TTS (144 dB SEL) for the Very High Frequency Cetaceans was estimated at 135 m (1 h) and 150 m (2 h). Finally, for the Phocid Pinnipeds the TTS (168dB SEL) was predicted at 456 m (1 h) and 616 m (2 h).

Level A Harassment (auditory injury/Permanent Threshold Shift, PTS) resulting from the VSP airgun array for Low-Frequency Cetaceans was predicted at 123 m based on the SPLpeak criterion. Based on the cumulative SEL criterion, the predicted Level A Harassment distances for active firing durations of 1.0 h and 2.0 h were 1.0 km and 2.0 km, respectively. For High-Frequency Cetaceans, Level A Harassment was predicted at 123 m based on the SPLpeak criterion, while the cumulative SEL criterion predicted distances of 123 m for active firing durations of 1.0 h and 2.0 h, respectively. For Very High-Frequency Cetaceans (Harbour Porpoise – VHF), Level A Harassment was predicted at 112 m based on the SPLpeak criterion and 123 m and 135 m based on the cumulative SEL criterion for active firing durations of 1.0 h and 2.0 h, respectively. For Phocid Pinnipeds (Monk Seal – PCW), Level A Harassment was predicted at 56 m based on the SPLpeak criterion and 112 m and 135 m based on the cumulative SEL criterion for active firing durations of 1.0 h and 2.0 h, respectively.

Drilling activities will take place directly within the South Adriatic Ionian Strait EBSA. Drilling noise is a continuous, low frequency sound. The maximum Level B Harassment threshold (120 dBrms) was noted as 91 m for all marine mammals. Level A Harassment was predicted for SEL for all hearing groups to 30 m, over a 24-hour drilling period (current proposed schedule identified within Section 6.6).

As identified in Section **Error! Reference source not found.**, vessel noise further has potential to induce disturbance to marine mammals, specifically when intra-cumulative impacts may arise (i.e., when drilling, vessel movement and VSP may occur concurrently) and zones of influences spatially overlap. Maximum distances whereby Level B Harassment (behavioral disturbance), injury or TTS may be reached is identified in the preceding sections. Transit of vessels will take place between the Igoumenitsa supply base and through the Ionian Archipelago IMMA and South Adriatic Ionian Strait EBSA; it is conservatively envisaged that up to 60 one-way transits will occur over the duration of the drilling campaign.

Discharges to the marine environment have the potential to cause temporal and localised changes, which may indirectly affect marine mammals through temporary effects on prey availability. Marine mammals will be most sensitive to discharges to the water column over the seabed (i.e., riser drilling discharges, cement

discharges, wastewater, drainage water, cooling water and ballast). Though due to the potential dive depth of sperm whales, individuals may overlap with plumes of discharges at the seabed (i.e., riserless drilling discharges, cement discharges, blowout preventer discharges).

Drill cuttings dispersion modelling concluded that suspended material may be transported away from the discharge location under the influence of prevailing currents, with the plume extent varying according to seasonal oceanographic conditions. For the physical presence of suspended drill cuttings in the water column, a Predicted No Effect Concentration (PNEC) of 100,000 ppb (equivalent to 100 mg/L) has been applied as a screening threshold within the ERMS/DREAM risk-assessment framework. Elevated concentrations of discharged elements and compounds (such as calcium carbonate) are predicted to be temporary, with environmental risk diminishing rapidly following termination of discharge activities due to dispersion and dilution processes within the open marine environment (see Section **Error! Reference source not found.**).

Metals within drilling fluids exhibit an overall very low bioavailability to marine animals, including marine mammals; bioaccumulation has however been documented in barium sulphate (barite) albeit with levels not high enough to harm species (Neff et al., 1987), and this compound is inert. This in combination with limited duration of exposure risk, concludes limited pathways for impacts to marine mammals to occur. Cement discharges are expected to be of low volumes and only occurring over short discharge durations. Noting the proposed well locations, offshore species are most likely to be impacted by discharges associated with drilling (i.e., drill cuttings, cement, etc.). It is unlikely that coastal species (i.e., Mediterranean monk seal) will overlap significantly with offshore discharge plumes, however noting worst-case distances associated with drill cuttings dispersion, overlap of individuals is plausible, if only for short durations. Routine discharges may occur during vessel transit; however all discharges will be under relevant best practice and performance standards. Marine mammals are highly mobile species; individuals are not expected to remain within discharge zones for any significant length of time. In addition, as noted, within an open ocean environment, discharged fluids are anticipated to rapidly disperse and dilute. As such there is limited potential for toxicity impacts to species that would impact the integrity of species populations over the course of the drilling programme. Any impacts that do occur to marine mammals and other megafauna and their prey species are expected to be short-term and localised, with recovery expected once individuals exit the discharge zone. It is acknowledged as stated within Section 6.7. that no planned discharge of radioactive material is predicted, based on embedded mitigation, no residual risk to marine mammals consequent of radioactive exposure is envisaged.

While marine mammals may respond to high light levels through behavioural disturbance, physiological impacts and through predator-prey relations. Studies have quantified potential penetration of light from vessels down to 200 m water depth, however offshore dispersion of artificial light is overall poorly understood and quantified (Marangoni et al., 2022). Marine mammal exposure to artificial light associated with drilling is expected to be limited, due to the mobile nature of individuals and short duration of the drilling campaign (expected duration of 67 days).

Any indirect impacts consequent of changes in prey availability is not foreseen to significantly impact marine mammals in the vicinity of the project. Marine mammals forage over large areas, with the Block area unlikely to represent a key foraging area for individuals. In addition, species are commonly generalist foragers with a number of prey options, should one be hindered consequent of project implementation. There is considered to be sufficient additional habitat available in the Ionian Sea and wider Mediterranean.

In addition, spatial disturbance and underwater noise impacts consequent of ROV operation is not anticipated to induce significant impacts to marine mammals. Such surveying is expected to be negligible when considered in the wider context of project activities, i.e., disturbance from drilling, VSP vessel presence, etc.

As within Section **Error! Reference source not found.**, the extent of an impact has been upgraded for certain activities where support vessel transit routes and impact zones of influences (based on modelling outcomes) may overlap with the Ionian Archipelago IMMA, due to the sensitivity of receptors within this area. Further Natura 2000 sites are located within proximity, however as stated in preceding sections, significant impacts to site integrity is not envisaged; such sites are located beyond the perceived zones of influence of VSP activities for high frequency cetaceans. It is further acknowledged that the overall drilling programme is limited in duration.

It is expected for the purpose of noisy activities (most impulsive noise sources [VSP activities]) that a marine mammal mitigation plan will be developed and implemented as appropriate. The plan will define the applicable mitigation measures, taking account of relevant ACCOBAMS guidance and regulatory requirements. During VSP activities specifically, soft-start procedures will be implemented and visual monitoring of marine mammals by a dedicated marine mammal observer will take place within a 500 m visual zone prior to the commencement of noisy works; passive acoustic monitoring will also be conducted. Furthermore, Vessel speeds may be reduced as much as reasonably practicable when transiting through the IMMA and the EBSA site. All relevant international best practice and legal frameworks are expected to be adhered to.

With regard to discharges, it is further assumed that all relevant best practices (i.e., development of Waste/Chemical Management Plans, adherence to Greek and international legal frameworks, low toxicity/low bioaccumulation potential chemicals to be used, etc.) will be implemented, where technically suitable. As above, such measures have been considered as part of project design/embedded mitigation. No planned discharge from the MODU or Project vessels shall be made if at any point a vessel is within the Ionian Archipelago IMMA or the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site.

In summary, with regard to their significance, impacts expected on marine mammals during the exploration drilling operations phase are assessed as negative (–) for all activities. The impacts range from negligible to low in magnitude (IN=1–4), extending from the project footprint to transboundary scales where relevant (EX=1–8), occurring immediately or in the short term (MO=2–4), temporary (PE=1–2), reversible to readily reversible (RV=1–2), with limited synergistic effects (SI=1–2), direct or indirect depending on the impact pathway (EF=1–4), irregular to continuous (PR=1–4), with immediate to short-term recovery (MC=1–2), and non-cumulative to cumulative (AC=1–4). Considering the high sensitivity of the valued receptor, **significant** impacts are predicted for direct and indirect underwater noise associated with Vertical Seismic Profiling (VSP) activities, reflecting the sensitivity of marine mammals to impulsive underwater noise. **Moderate** impacts are associated with drillship dynamic positioning, MODU drilling and wellhead/casing installation, discharges of drilling fluids and cuttings, cement discharges, pipe dope use, blowout preventer testing, and lighting from the MODU. The remaining activities are assessed as **minor** due to their localized, temporary and reversible nature. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are reduced to **moderate** for VSP activities and **minor** for all

remaining activities. Please refer to the table below for the detailed impact quantification by activity for the exploration drilling operations phase.

| Impacts on marine mammals                                                                            |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |                                    |

\*Notes: though it is appreciated radioactive storage and chemical use may induce long-term irreversible impacts to marine mammals, under standard operational conditions significant discharge of such materials is not envisaged. Such that there is deemed to be limited potential for interaction with marine mammals when best practice storage procedures are implemented.

#### 10.1.5.2.4.3 Demobilisation and abandonment phase

The demobilisation and abandonment phase has the potential to induce impacts to marine mammals through the following principal pathways: underwater noise, physical presence and associated spatial disturbance/elevated collision risk, discharges and subsequent impacts through changes in water quality, toxicity and bioaccumulation and indirect impacts through changes in prey availability etc.

During the demobilisation and abandonment phase, there will be localised spatial disturbance within the Block area associated with the removal of temporary infrastructure, surface handling operations and demobilisation of the MODU.

The impacts to marine mammals consequent of elevations in vessel presence (including MODU) and associated underwater noise impacts are outlined in Section **Error! Reference source not found..** It is acknowledged that the demobilisation and abandonment phase will be short in (approximately 10d) with only temporary impacts envisaged. Furthermore, this will occur in tandem with the cessation of drilling activities and other noisy activities associated with prior phases. Additionally, species are expected to be habituated to the pre-existing vessel presence within the Block area consequent of earlier phases. Following the cessation of works, individuals are expected to return to the Block area in relatively short timeframes. Following demobilisation, disturbance from Project vessels and activities will cease and conditions are expected to return towards baseline.

Impacts with regard to discharges to the marine environment are discussed in Section **Error! Reference source not found.** There is potential that marine discharges associated with demobilisation may impact local water quality and infer indirect impacts to marine mammals. Marine mammals are highly mobile species; individuals are not expected to remain within discharge zones for any significant length of time. In addition, as noted, within an open ocean environment, discharged fluids are anticipated to rapidly disperse and dilute. As such there is limited for potential for toxicity impacts to species that would impact the integrity of species populations over the course of the drilling programme. Any impacts that do occur to marine mammals and other megafauna and their prey species are expected to be limited, with rapid recovery expected once individuals exit the discharge zone.

Well plugging is unlikely to infer significant impacts to marine mammals attributed to water depth, discharge volumes and likelihood of marine mammals overlapping with such zones of influence. However, noting the dive depth of certain species, overlap may be possible for deep diving species. As a result, there may be localised declines in water quality with potential to result in indirect impacts through changes in prey availability. However as detailed in preceding sections, significant implications to foraging success is not expected attributed to sufficient additional habitat and prey options available to individuals.

Overall, the impacts are characterised by negligible impact magnitude (IN=1), confined to the project footprint (EX=1), occurring immediately or in the short term (MO=2-4), temporary (PE=1-2), reversible to readily reversible (RV=1-2), with limited synergistic effects (SI=1-2), direct or indirect depending on the activity (EF=1-4), irregular to intermittent (PR=1-4), with immediate to short-term recovery (MC=1-2), and generally non-cumulative to weakly cumulative (AC=1-4). Considering the high sensitivity of the valued receptor, all identified impacts are assessed as **minor** in significance. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are also expected to remain **minor**.

| Impacts on marine mammals                                                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.5.2.5 Sea turtles

#### 10.1.5.2.5.1 Drilling preparation and mobilisation phase

The mobilisation of the MODU (Stena DrillMAX) via self-propulsion to Block 2 and any associated support / supply vessels has the potential to induce temporary spatial disturbance to sea turtles, eliciting behavioural disturbance and potential collision risk. Such behavioural disturbance may include evasive manoeuvres (i.e., diving or changes in swimming direction). The capacity of sea turtles to induce evasive behaviour is largely dependent on vessel speed (Hazel et al., 2007).

Turtles spend 20 to 30% of their time at the sea surface for respiration, basking, feeding, orientation and feeding (Lutcavage et al., 2017). Studies show that coastal zones in particular can be hotspots for vessel strikes with evidence from strandings in Florida indicating that inlets and channels associated with ports are of particular concern (Welsh and Witherington 2023). Vessel strikes are a documented cause of mortality in sea turtles, with collisions potentially occurring with vessels of all sizes. As for marine mammals, tanker / cargo vessels may be the most common vessel whereby collisions occur for sea turtles (Laist et al., 2001). A reduced vessel speed is proven to significantly reduce the risk of collision to marine megafauna species, including sea turtles. At speeds faster than 2 knots, some turtles will flee an approaching vessel, but most will not avoid a collision (Hazel et al., 2007; Schoeman et al., 2020). However, it is noted that overall, the drilling preparation and mobilisation phase is temporary and short in duration (< 15d), with vessel transit limited to 2-6 days. A single MODU is not expected to significantly increase spatial disturbance to sea turtles when considered in the context of pre-existing vessel traffic within the Ionian Sea, where well defined shipping corridors already exist, though due to the sensitivity of receptors a precautionary approach will be taken with regard to the impact assessment.

Disturbance may further be induced from elevations in underwater noise attributed to mobilisation of the MODU and associated support / supply vessels. Sea turtle sensitivity to underwater noise is largely poorly understood. It is assumed at the time of writing that sea turtles hearing is more similar to that of fish species, compared to marine mammal sensitivity. To assess the sensitivity of sea turtles to underwater noise

generated by the Project, an underwater acoustic modelling was undertaken under representative operational hydrodynamic conditions.

It is acknowledged that species most likely to overlap with project activities, most notably coastal transit of vessels, or whereby zones of influence may overlap with more coastal areas, include the green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) turtle.

It is estimated that during the approximately 7-hour transit of a platform supply vessel, from the Port of Igoumenitsa to Block 2 at an open-water maximum speed of 14 knots, an individual animal experiences a brief pass-by exposure (0.5 to 1 hour). The threshold for aversive behavioural for sea turtles (170 dBrms) is predicted to reach a distance of 91 m. Upon arrival at the project site or at the port of Igoumenitsa, as the vessel is assumed to reduce speed (4 knots) for manoeuvring, this behavioural response zone reduces to 31 m. As a result, only highly localised impact ranges are predicted during the drilling preparation and mobilisation phase.

Any indirect impacts consequent of changes in prey availability is not foreseen to significantly impact sea turtles in the vicinity of the project. Sea turtles forage over large areas, with the Block not identified from the available baseline information as an important concentration area for foraging or nesting, although individuals may transit through or forage within the wider area. There is considered to be sufficient additional habitat available in the Ionian Sea and wider Mediterranean, with loggerheads primarily documented foraging in neritic grounds along the Tunisian shelf and Adriatic Sea, and green turtles in the eastern Mediterranean.

Support/ supply vessels may transit through the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003), designated for green and loggerhead turtle; the site is specifically noted for nesting behaviour for loggerhead turtles. It is appreciated the South Adriatic Ionian Strait EBSA noted provisioning habitats for loggerhead turtles. Vessel movements associated with the Project represent a temporary and limited addition to the existing shipping activity within the Ionian Sea. Project vessels will follow established transit routes and implement the relevant vessel management and fauna protection measures, including operating at speeds not exceeding 14 knots (or lower where operationally required), maintaining appropriate stand-off distances from observed sea turtles, and avoiding unnecessary disturbance where safe and practicable. Consequently, the temporary increase in vessel traffic is not expected to result in significant disturbance to sea turtles.

In summary, with regard to their significance, impacts expected on sea turtles during the mobilisation phase are assessed as **negative** (–) for all activities, with negligible impact magnitude (IN=1), confined to the project footprint (EX=1), occurring immediately (MO=4), temporary (PE=1), readily reversible (RV=1), with limited synergistic effects (SI=2), direct or indirect depending on the impact pathway (EF=4), irregular (PR=1), with immediate recovery (MC=1), and non-cumulative (AC=1). Considering the high sensitivity of the valued receptor, all identified impacts are assessed as **minor** in significance. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are expected to remain **minor**. Please refer to the table below for the detailed impact quantification by activity for the mobilisation phase.

| Impacts on sea turtles                                                                     |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.5.2.5.2 Exploration drilling operations phase

During the exploration drilling and operations phase, underwater noise and spatial disturbance is the greatest concern for sea turtles, though additional pathways may exist from discharges into the marine environment.

The physical presence of the MODU and transit of vessels is not envisaged to induce significant spatial disturbance over the course of the exploration drilling operations phase. This is attributed to pre-existing vessel traffic within the Ionian Sea, alongside overall low likelihood of significant overlap of individuals with the offshore project location. The Block location is envisaged as more of a transit route for individuals, with only transient presence anticipated.

Elevations in underwater noise will arise from MODU drilling activities, MODU operation, support / supply vessel operations (including DP) and VSP activities during this phase. Impacts may arise in the form of behavioural disturbance (i.e., masking) or direct injury. Underwater noise modelling (see Section 6.12.3.4) has also been undertaken for the VSP and drilling activities, alongside noise generated from vessel movements.

While each VSP operation is allocated a 12-hour survey window for tool deployment and testing, the active airgun discharge is limited to approximately 130 shots per well section, at 15-second firing intervals. This results in an active firing duration of approximately 32.5 minutes (0.5 hours) per section, with a contingency envelope evaluated up to 1.0 or 2.0 hours. Over these time periods of VSP airgun arrays, mortality (210 dB SEL) for sea turtles is predicted 135 m for 0.5, 147 m (Summer Mean) for 1 h, and 259 m (Summer Mean) for 2 h, whilst the SPLpeak is predicted at 125 m. With regards to the sea turtles aversive behaviour (175dB) occurrence it is predicted at maximum 295 m.

Drilling activities will take place directly within the South Adriatic Ionian Strait EBSA. Drilling noise is a continuous, low frequency sound. Only localised impact areas were concluded for sea turtles in relation to aversive behaviour (30m maximum distance).

As identified in Section **Error! Reference source not found.**, vessel noise further has potential to induce disturbance to sea turtles, specifically when intra-cumulative impacts may arise (i.e., when drilling, vessel movement and VSP may occur concurrently) and zones of influences spatially overlap. However, only relatively localised impact areas were concluded for support / supply vessel movements when compared to other marine megafauna species (i.e., low frequency cetacean species).

Discharges to the marine environment may cause temporary and localised changes in water quality, which may indirectly affect sea turtles through temporary effects on prey availability. Sea turtles will be most sensitive to discharges to the water column over the seabed (i.e., riser drilling discharges, cement discharges, wastewater, drainage water, cooling water and ballast); significant overlap with discharge plumes of discharges at the seabed is not envisaged noting water depth and expected dive depth of species. Drill cuttings dispersion modelling concluded that suspended material may be transported away from the discharge location under the influence of prevailing currents, with the plume extent varying according to seasonal oceanographic conditions. For the physical presence of suspended drill cuttings in the water column, a Predicted No Effect Concentration (PNEC) of 100,000 ppb (equivalent to 100 mg/L) has been applied as a screening threshold within the ERMS/DREAM risk-assessment framework. Elevated concentrations of discharged elements and compounds (such as calcium carbonate) are predicted to be temporary, with environmental risk diminishing rapidly following termination of discharge activities due to dispersion and dilution processes within the open marine environment (see Section **Error! Reference source not found.** & 10.1.4.5).

Metals within drilling fluids exhibit an overall very low bioavailability to marine animals, including sea turtles; bioaccumulation has however been document in barium sulphate (barite) albeit with levels not high enough to harm species (Neff et al., 1987), and it is an inert compound. This in combination with limited duration of exposure risk, concludes limited pathways for impacts to sea turtles to occur. Cement discharges are expected to be of low volumes and only occurring over short discharge durations. Noting the proposed well locations, it is unlikely that sea turtles will overlap significantly with offshore discharge plumes (i.e., drill cuttings discharges), however noting worst-case distances associated with drill cuttings dispersion, overlap of individuals is plausible, if only for short durations during migration. Routine discharges may occur during vessel transit; however all discharges will be under relevant best practice and performance standards.

Discharged fluids are anticipated to rapidly disperse and dilute. As such there is limited for potential for toxicity impacts to species that would impact the integrity of species populations over the course of the drilling programme. Any impacts that do occur to sea turtles and their prey species are expected to be acute, with rapid recovery expected once individuals exit the discharge zone. It is acknowledged as stated within Chapter 4, that no planned discharge of radioactive material is predicted, based on embedded mitigation, no residual risk to sea turtles consequent of radioactive exposure is envisaged.

Marine turtle behaviour may be altered through artificial light impacts, or through predator prey relations. While impacts to turtle nesting behaviour is noted, acknowledging the distance from shore of the MODU, no coastal impacts are envisaged. Sea turtle exposure to artificial light associated with drilling is expected to be limited, noting the transient nature of individuals within the Block location, the mobile nature of individuals and short duration of the drilling campaign (maximum duration of 90 days).

Any indirect impacts consequent of changes in prey availability is not foreseen to significantly impact sea turtles in the vicinity of the project. Sea turtles forage over large areas, with the Block area unlikely to

represent a key foraging area for individuals, noting earlier preferred foraging grounds of individuals (Section **Error! Reference source not found.**).

In addition, spatial disturbance and underwater noise impacts consequent of ROV operation is not anticipated to induce significant impacts to sea turtles. Such surveying is expected to be negligible when considered in the wider context of project activities, i.e., disturbance from drilling, VSP vessel presence, etc.

As within Section **Error! Reference source not found.**, the extent of an impact has been upgraded for certain activities where transit routes and impact zones of influences (based on modelling outcomes) may overlap with Natura 2000 sites designated for sea turtles.

It is expected for the purpose of noisy activities (most impulsive noise sources [VSP activities]) that a marine mammal (and other megafauna) mitigation plan will be developed and implemented as appropriate. The plan will define the applicable mitigation measures, taking account of relevant ACCOBAMS guidance and regulatory requirements.. The plan will further consider other megafauna species, including sea turtles due to sensitivity of the receptor. During VSP activities specifically, soft-start procedures will be implemented and visual monitoring of marine megafauna, including sea turtles by a dedicated marine megafauna observer will take place within a 500 m visual zone prior to the commencement of noisy works. Such measures have been considered as part of project design/embedded mitigation.

In addition, vessel speeds may be reduced as much as reasonably practicable when transiting through the the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site and the EBSA site. Applicable legal requirements and relevant Project-adopted good-practice measures will be implemented.

With regard to discharges, it is further assumed that all relevant best practices (i.e., development of Waste/Chemical Management Plans, adherence to Greek and international legal frameworks, low toxicity/low bioaccumulation potential chemicals to be used, etc.) will be implemented, where technically suitable. As above, such measures have been considered as part of project design/embedded mitigation. No planned discharge from the MODU or Project vessels shall be made if at any point a vessel is within the Ionian Archipelago IMMA or the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site.

In summary, with regard to their significance, impacts expected on sea turtles during the exploration drilling operations phase are assessed as negative (–) for all activities. The impacts range from negligible to low in magnitude (IN=1–4), extending from the project footprint to transboundary scales where relevant (EX=1–8), occurring immediately or in the short term (MO=2–4), temporary (PE=1–2), reversible to readily reversible (RV=1–2), with limited synergistic effects (SI=1–2), direct or indirect depending on the impact pathway (EF=1–4), irregular to continuous (PR=1–4), with immediate to short-term recovery (MC=1–2), and non-cumulative to cumulative (AC=1–4). Considering the high sensitivity of the valued receptor, **Significant** impacts are predicted for direct and indirect underwater noise associated with Vertical Seismic Profiling (VSP) activities, reflecting the sensitivity of sea turtles to impulsive underwater noise. **Moderate** impacts are associated with drillship dynamic positioning, MODU drilling and wellhead/casing installation, discharges of drilling fluids and cuttings, cement discharges, pipe dope use, blowout preventer testing, and lighting from the MODU. The remaining activities are assessed as **Minor** due to their localized, temporary and reversible nature. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are reduced to **Moderate** for VSP activities and **Minor** for all remaining activities.

Please refer to the table below for the detailed impact quantification by activity for the exploration drilling operations phase.

| Impacts on sea turtles                                                                               |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |                                    |

\*Notes: though it is appreciated radioactive storage and chemical use may induce long-term irreversible impacts to sea turtles, under standard operational conditions significant discharge of such materials is not envisaged. Such that there is deemed to be limited potential for interaction with marine mammals when best practice storage procedures are implemented.

#### 10.1.5.2.5.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, there will be localised spatial disturbance within the Block area in association with the removal of temporary infrastructure, surface handling operations and demobilisation of the MODU.

Impacts regarding underwater noise and vessel presence (including MODU transit) is outlined in Section **Error! Reference source not found..** It is acknowledged that the demobilisation and abandonment phase will be short in (approximately 10d) only temporary impacts envisaged. Furthermore, this will occur in tandem with the cessation of drilling activities and other noisy activities associated with prior phases. Additionally, species are expected to be habituated to the pre-existing vessel presence within the Block area consequent of earlier phases. Following demobilisation, disturbance from Project vessels and activities will cease and conditions are expected to return towards baseline. As such once full demobilisation has occurred, a positive impact may be concluded, though noting the limited footprint of the project, this is expected to be negligible in the wider context of the Ionian Sea.

There may further be discharges associated with MODU demobilisation and circulation, impacts are parallel to those discussed in Section **Error! Reference source not found..** No planned discharge from the MODU or Project vessels shall be made if at any point a vessel is within the Ionian Archipelago IMMA or the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site.

Well plugging is highly unlikely to induce significant impacts to sea turtles attributed to water depth and dive depth of individuals.

In summary, with regard to their significance, impacts expected on sea turtles during the demobilisation and abandonment phase are assessed as negative (–) for all activities. As with the previous phases, the potential for vessel transit through sensitive sea turtle areas during demobilisation has been reflected in the assessment of impact extent where relevant. Overall, the impacts are characterised by negligible impact magnitude (IN=1), confined to the project footprint (EX=1), occurring immediately or in the short term (MO=2–4), temporary (PE=1–2), reversible to readily reversible (RV=1–2), with limited synergistic effects (SI=1–2), direct or indirect depending on the impact pathway (EF=1–4), irregular to intermittent (PR=1–4), with immediate to short-term recovery (MC=1–2), and generally non-cumulative to weakly cumulative (AC=1–4). In relation to vessel transit through the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site and the South Adriatic Ionian Strait EBSA, the mitigation measures described in Section 10.1.5.2.5.1 will be implemented. The temporary and localized nature of the demobilisation activities, together with these mitigation measures, means that all identified impacts are assessed as **minor** in significance. Following the implementation of the prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are also expected to remain **minor**. Please refer to the table below for the detailed impact quantification by activity for the demobilisation and abandonment phase.

| Impacts on marine mammals                                                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.5.3 Avifauna

The main bird groups present in the project area are pelagic seabirds and migratory birds. The overall direct effects by the operations on the avifauna present in the area are expected to be associated with physical presence of vessels and their local temporary changes to the surrounding environment which include the presence of overhead infrastructures (vessels), their artificial lighting and changes of the water quality and seabird prey availability due to their operation (Rinconi et al. 2015).

The presence of overhead infrastructure at sea poses a collision risk to both seabirds and migratory landbirds, which may result in mortality or injuries. This risk is additionally enhanced by the attraction or disorientation effect on birds of the artificial lighting or in the cases of adverse weather conditions that reduce visibility.

For the migratory landbirds, passerine species, most of which migrate in large numbers at night, the collision risk is particularly elevated. Hüppop et al. (Hüppop et al. 2016) have estimated an annual mortality of 150 dead birds, mainly thrushes, European Starlings and other passerines, at a single unmanned tall offshore research platform in the North Sea and a potential cumulative annual mortality of hundreds of thousands of birds at offshore human structures in the North Sea. The attraction of migratory landbirds to artificial lighting at night may cause their circulation around the source of light, leading to exhaustion, energy depletion and potentially death (e.g. Russell et al. 2005). On the other hand, offshore vessels and platforms provide unique offshore resting and roosting sites for migratory landbirds and several seabird species, e.g. gulls and terns. Some migratory landbirds use vessels as stopover sites to rest and recover from fatigue before continuing their migration.

Among seabird species, petrels and shearwaters are considered to be the most susceptible to the adverse effects of the offshore artificial lights at night (ALAN), which include disorientation, attraction and avoidance. In the Mediterranean, light pollution has been associated with strandings of the Yelkouan Shearwater (*Puffinus yelkouan*), Scopoli's Shearwater (*Calonectris diomedea*) in the vicinity of their colonies on Malta, as well as, selection of breeding sites of the European Storm-petrel (*Hydrobates pelagicus*) with reduced light pollution (Laguna et al. 2014). Shearwater and petrel fledglings are inexperienced with the artificial light and are therefore particularly affected by the attraction and disorientation caused by the artificial light (Fontaine et al. 2011, Rodríguez et al. 2017, Austad et al. 2023, Imber et al. 1975). Collision with vessels may occur when seabirds are disoriented by bright vessel lights at night or under adverse weather conditions. Risk of collision with and stranding at sea primarily affects smaller seabird species (petrels) and some large species which may become disoriented (shearwaters) (Rinconi et al. 2015).

The physical presence of vessels could also cause an avoidance effect increasing the energy expenditure for some seabird species, however these effects are considered to be limited due to the temporary Project presence and the existing levels of vessel traffic along shipping routes connecting Greece and Italy and the Adriatic and Ionian Seas.

Artificial lights at night (ALAN) in the marine environment attract plankton, invertebrates and fish (Fobert et al. 2023), therefore the waters in the vicinity of offshore platforms may have increased abundance of seabird prey species and consequently, potentially increased seabird abundance, however the mechanism behind the increase of prey availability is not well understood (Rinconi et al. 2015). Therefore, ALAN may indirectly increase the abundance of seabirds of offshore platforms, resulting in the increased collision risk. However, based on the available data the project area has not been identified as an important seabird foraging area, therefore the temporary and localized presence of vessels, the local changes in the quality of water, prey availability due to ALAN or permitted operational discharges are not considered to have a significant effect on the seabirds in terms of foraging habitat and prey availability and quality, as well as collision risk or displacement.

Helicopter operations may cause disturbance to birds in the area of operation and in extreme cases may lead to bird strikes. In general, bird species most likely to be involved in bird strikes with helicopters include species which are locally present in large numbers or large and heavy birds e.g. vultures, geese, gulls, etc. It is however considered that following standard safety procedures to avoid bird strikes, the risk and impact is minimal.

Provided below are the assessment of impact on avifauna during each of the project phases.

#### 10.1.5.3.1 Drilling preparation and mobilisation phase

The drilling preparation and mobilisation phase has the potential to induce impacts to avifauna through the following principal pathways:

- vessel collisions caused by the physical presence of the vessels and/or artificial light at night (ALAN) at night and in adverse weather conditions,
- increased energy cost leading to exhaustion or starvation due to attraction, avoidance or disorientation by the presence of the vessels and/or artificial light at night (ALAN) in night,
- provision of offshore resting or roosting sites onboard vessels.

The mobilisation of the MODU (Stena DrillMAX) via self-propulsion to Block 2 and any associated support / supply vessels has the potential to induce temporary localized spatial disturbance or alterations to avifauna, which may include, depending on the bird species and individuals, attraction/avoidance of the vessels by their physical presence, as well as, attraction/avoidance/disorientation by vessels' artificial lights at night (ALAN). If the mobilisation of the vessels coincides with the spring or autumn migration periods, the negative impacts may include collisions of migratory birds with the vessels, increased migration energy cost due to attraction/avoidance/disorientation, while positive impacts include provision of additional offshore resting or roosting sites for migratory birds. If the mobilisation of the vessels coincides with the breeding seasons of the pelagic seabird species (from spring until autumn) the impacts may include attraction/avoidance/disorientation of seabirds at night increasing energy cost and in extreme cases

collisions with the vessels, with increased risks during the fledging period of the burrow-nesting seabirds (Scopoli's and Yelkouan Shearwaters, European Storm-petrel).

The location of the onshore logistics / supply base at Igoumenitsa is located in the vicinity Special Protection Area "Ygrotopos ekvolon Kalama kai nisos Prasoudi" (GR2120005) that host numerous breeding, wintering and migratory waterbird, wader, heron/egret, cormorant, raptor, gull/tern and passerine species which may experience temporary disturbance; however, significant effects are not expected given that Project activities will occur within the existing operational port area and represent a temporary addition to established port activity.

In summary, with regard to their significance, the expected impacts on avifauna associated with the drilling preparation and mobilisation phase are assessed as **negative** (-) for the majority of impacts apart from the provision of resting/roosting sites which is assessed as **positive** (+). The above impacts have been considered transboundary because they have an effect on numerous migratory species, as well as, seabird species that are regularly present in the wider area of the Ionian Sea and the Adriatic Sea. The impacts of collision with vessels and increased energy cost/exhaustion/starvation are qualified as **minor**, while the provision of additional resting/roosting sites for migratory birds onboard project vessels is qualified as positive. Please refer to the below table for a breakdown of impact quantification per activity for the drilling preparation and mobilisation phase.

| Impacts on avifauna                                                                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

### 10.1.5.3.2 Exploration drilling operations phase

The exploration drilling and operations phase has the potential to induce impacts to avifauna through the following principal pathways:

- vessel collisions caused by the physical presence of the vessels and/or artificial light at night (ALAN) at night and in adverse weather conditions,
- collision risk due to helicopter transfers between heliport and MODU

- increased energy cost leading to exhaustion or starvation due to attraction, avoidance or disorientation by the presence of the vessels and/or artificial light at night (ALAN) at night,
- provision of offshore resting or roosting sites onboard vessels

The exploration drilling involves drilling of a single (1) well. The expected duration of the exploration drilling activity is approximately 57-67 days with the design envelope allowing the maximum duration of up to 90 days. Therefore, the drilling operations, as well as, their direct impacts on avifauna will be temporary and spatially limited to the area around the drilling location and the supply routes of the supply vessels and helicopters.

The physical presence of the MODU and associated support / supply vessels, the MODU drilling operations and the transit of the support/supply vessels have the potential to induce temporary localized spatial disturbance or alterations to avifauna, which may include, depending on the bird species and individuals, attraction/avoidance of the vessels by their physical presence, as well as, attraction/avoidance/disorientation by vessels' artificial lights at night (ALAN). If the operations of the aforementioned vessels during the drilling phase coincide with the spring or autumn migration periods, the negative impacts may include collisions of migratory birds with the vessels, increased migration energy cost due to attraction/avoidance/disorientation, while positive impacts include provision of additional offshore resting or roosting sites for migratory birds. If these operations take place during the breeding seasons of the pelagic seabird species (from spring until autumn), the impacts may include attraction/avoidance/disorientation of seabirds at night increasing energy cost and in extreme cases collisions with the vessels, with increased risks during the fledging period of the burrow-nesting seabirds (Scopoli's and Yelkouan Shearwaters, European Storm-petrel).

Additionally, artificial lighting at night (ALAN) of MODU may temporarily attract seabird prey species to the drilling area, thus potentially temporarily increasing the food availability and consequently the abundance of seabirds in the vicinity of MODU. An increase in the seabird abundance in the vicinity of MODU would increase the risk of seabird collisions with MODU and support/supply vessels in the area.

Helicopter operations during transfers between heliport and MODU will follow the standard safety procedures, therefore the risk of bird strikes as well as the disturbance of bird are considered to be minimal.

The discharges at the seabed and the underwater noise are not expected to have any significant direct or indirect impacts on the birds, because the bird species present in the area either fly or use the sea surface for resting or the sea surface and the very top layer of the water column for catching prey.

Surface discharges of MODU and support vessels, including waste, wastewater, sanitary water, deck drainage, ballast and discharges of the desalination unit, will follow relevant best practice and performance standards, are expected to create a very temporary and minor changes to the water quality and directly or indirectly prey availability for the seabirds that will rapidly disperse and dilute. Therefore, negligible in magnitude and very temporary impacts on seabirds are expected in terms of the water quality and seabird prey availability.

Based on relatively low abundance and density of birds in the drilling area and the remoteness of the area, it is considered unlikely that the abundance of birds at MODU during the drilling operations will increase significantly, because there are numerous other much better-quality roosting and foraging habitats available in the coastal areas of the Ionian Sea. Therefore, the abundance of seabirds at the drilling location due to

changes in the prey availability and the availability of the roosting sites is not expected to change significantly and consequently the significance of expected impacts is not expected to change significantly due to these parameters.

In summary, with regard to their significance, the expected impacts on avifauna associated with the exploration drilling operations phase are assessed as **negative** (-) for the majority of impacts apart from the provision of resting/roosting sites which is assessed as positive (+). The above impacts have been considered transboundary because they have an effect on numerous migratory species, as well as, seabird species that are regularly present in the wider area of the Ionian Sea and the Adriatic Sea. The impacts of collision with vessels and increased energy cost/exhaustion/starvation of the MODU operation during the exploration drilling operations phase are qualified as **moderate**, while the impacts of collision with vessels and increased energy cost/exhaustion/starvation due to the operation of the support/supply vessels are qualified as **minor**. The provision of additional resting/roosting sites for migratory birds onboard MODU and support/supply vessels is qualified as **positive**. Please refer to the below table for a breakdown of impact quantification per activity for the exploration drilling operations phase. It should be noted that the impacts of collision with vessels and increased energy cost/exhaustion/starvation of the MODU and support/supply vessels are associated with both the physical presence and the ALAN of the vessels, therefore the impact quantifications for both have been assessed together but the same quantification has been assigned to both activities/elements.

Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

| Impacts on avifauna                                                                                                               |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |        |                            |                     |                                  |

#### 10.1.5.3.3 Demobilisation and abandonment phase

The demobilisation and abandonment phase has the potential to induce impacts to avifauna through the following principal pathways:

- vessel collisions caused by the physical presence of the vessels and/or artificial light at night (ALAN) at night and in adverse weather conditions,
- increased energy cost leading to exhaustion or starvation due to attraction, avoidance or disorientation by the presence of the vessels and/or artificial light at night (ALAN) in night,
- provision of offshore resting or roosting sites onboard vessels.

During the demobilisation and abandonment phase, there will be localised spatial disturbance within the Block area associated with the removal of temporary infrastructure, surface handling operations and demobilisation of the MODU. Therefore, only temporary and spatially localized impacts are expected.

Following the termination of drilling operations the MODU and the support/supply vessels will leave the project area. Similarly to the mobilization phase, the transit of the vessels has the potential to induce temporary localized spatial disturbance or alterations to avifauna, which may include, depending on the bird species and individuals, attraction/avoidance of the vessels by their physical presence, as well as, attraction/avoidance/disorientation by vessels' artificial lights at night (ALAN). If the demobilisation and abandonment phase coincides with the spring or autumn migration periods, the negative impacts may

include collisions of migratory birds with the vessels, increased migration energy cost due to attraction/avoidance/disorientation, while positive impacts include provision of additional offshore resting or roosting sites for migratory birds. If the demobilisation and abandonment phase coincides with the breeding seasons of the pelagic seabird species (from spring until autumn) the impacts may include attraction/avoidance/disorientation of seabirds at night increasing energy cost and in extreme cases collisions with the vessels, with increased risks during the fledging period of the burrow-nesting seabirds (Scopoli's and Yelkouan Shearwaters, European Storm-petrel).

In summary, with regard to their significance, the expected impacts on avifauna associated with the demobilisation and abandonment phase are assessed as **negative** (-) for the majority of impacts apart from the provision of resting/roosting sites which is assessed as **positive** (+). The above impacts have been considered transboundary because they have an effect on migratory species, as well as, seabird species that are regularly present in the wider area of the Ionian Sea and the Adriatic Sea. The impacts of collision with vessels and increased energy cost/exhaustion/starvation are qualified as **minor**, while the provision of additional resting/roosting sites for migratory birds onboard project vessels is qualified as **positive**. Please refer to the below table for a breakdown of impact quantification per activity for the demobilisation and abandonment phase.

| Impacts on avifauna                                                                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

#### 10.1.5.4 Areas of the National System of Protected Areas

The Asopus-1 exploration well does not fall within any area of the national system of protected areas.

The closest Natura 2000 sites to the Asopus 1 exploration well site are the Marine area of the Diapontia islands Special Area of Conservation (SAC) (GR2230010) and the Diapontia Islands: Othoni, Ereikousa, Mathraki and rocky islets Special Protection Area (SPA) (GR2230008), both located approximately 44 km northeast from the Project. The Costa Otranto - Santa Maria di Leuca SAC (IT9150002) is located approximately 53 km northwest away in Italy. The Ugento Coast SAC (IT9150009) is located in Italy at a distance of approximately 66 km northwest from the exploration well. The Gallipoli Coast and St. Andrea Island SPA/SAC (IT9150015) is located approximately 80 km northwest from the well.

#### 10.1.5.4.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, transit and positioning of MODU and support vessels can have impacts on the protected areas from the non-impulsive underwater noise produced by the engines and propellers and from the possibility of collision with marine animals. The Port of Igoumenitsa will serve as the operational base for Platform Supply Vessel (PSV) movements supporting the offshore drilling operations. Baseline conditions indicate that the project area is already subject to frequent shipping activities. The impacts arising from the additional vessel transits generated by the proposed exploration well are expected to have moderate effects on protected areas.

| Mobilisation of MODU to well site – power generation (direct underwater noise disturbance) | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 1             | 1                 | 19                    | Negligible | High                       | MINOR               |

#### 10.1.5.4.2 Exploration drilling operations phase

During the drilling operations phase, impacts to areas of the national system of protected areas are expected to arise from discharge of water based fluids and cuttings near sea surface (drilling with riser), cement discharges near sea surface from tank wash out, discharges of drainage water (deck drainage, fire water, bilge water and slop water) from MODU and support/supply vessels, discharges of ballast from MODU and support/supply vessels, vertical seismic profile (VSP) activities and support activities (movement of support vessels). As the project area does not fall within any protected areas and the closest one is approximately 44 km northeast from the Project, the impacts are expected to be minor to moderate.

Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

#### 10.1.5.4.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, no significant impacts on areas of the national system of protected areas are expected. Offshore activities will be limited to the removal of the temporary subsea structure and transit of the MODU and support vessels.

#### 10.1.5.5 Forests and wooded areas

No significant adverse impacts on forests and wooded areas are expected. The proposed project is located offshore and the shorebase facilities of the Project do not fall within the boundaries of the ratified and published forest map of Igoumenitsa.

#### 10.1.5.6 Other Significant Natural Areas

The Project under assessment is located within the South Adriatic Ionian Strait Ecologically or Biologically Significant Marine Area (EBSA).

The closest designated Important Marine Mammal Area (IMMA) to the project area is the Ionian Archipelago IMMA, located approximately 37 km east of the Asopus-1 exploration well. In the broader regional context, other formally designated IMMAs include the Hellenic Trench, the Gulf of Ambracia, and the Gulf of Corinth.

The closest Cetacean Critical Habitat (CCH) to the project area is the Sazani Island-Karaburun Peninsula, located approximately 72 km north from the exploration well. The closest Important Shark and Ray Area to the project area is the Santa Maria di Leuca ISRA, located approximately 20 km west/southwest from the exploration well. The Western Apulian Coast ISRA is located approximately 56 km northwest from the exploration well. The closest Key Biodiversity Area to the project area is the Diapontia islands (Othonoi, Ereikousa, Mathraki) and surrounding islets KBA (2943), located approximately 40 km northeast from the exploration well (see section 8.5.4).

#### 10.1.5.6.1 Drilling preparation and mobilisation phase

The project area falls within the South Adriatic Ionian Strait (EBSA). The designation recognizes the ecological importance of the area as habitat for Cuvier's beaked whale (*Ziphius cavirostris*), giant devil ray (*Mobula mobular*), striped dolphin (*Stenella coeruleoalba*), Mediterranean monk seal (*Monachus monachus*), and loggerhead sea turtle (*Caretta caretta*). As abovementioned, in the close vicinity of the project there are other areas that protect marine mammals, sharks, sea turtles and marine fauna. The impacts on other significant natural areas during drilling preparation and mobilisation phase are expected to be consistent to those on marine mammals (10.1.5.2.4.1), sea turtles (10.1.5.2.5.1), and fish fauna (10.1.5.2.3.1).

#### 10.1.5.6.2 Exploration drilling operations phase

During the drilling operations phase, impacts to other significant natural areas are expected to be similar to the impacts on marine mammals (10.1.5.2.4.2), sea turtles (10.1.5.2.5.2), and fish fauna (10.1.5.2.3.2).

#### 10.1.5.6.3 Demobilisation and abandonment phase

As the project area falls within the South Adriatic Ionian Strait (EBSA), the impacts during the demobilisation and abandonment phase are consistent with those on marine mammals (10.1.5.2.4.3), sea turtles (10.1.5.2.5.3), and fish fauna (10.1.5.2.3.3).

### 10.1.6 Impacts on Air Quality

#### 10.1.6.1 Drilling Preparation and Mobilization Phase

During the drilling preparation and mobilisation phase, impacts on air quality will arise from the mobilisation of MODU to the well site, vessel transits, power generation on the MODU, helicopter operations, and the establishment of temporary onshore logistics facilities at the Port of Igoumenitsa. Emissions will primarily consist of combustion-related pollutants, including nitrogen oxides (NO<sub>x</sub>), sulphur oxides (SO<sub>x</sub>), carbon monoxide (CO), particulate matter (PM), and greenhouse gases (GHGs), associated with marine engines and mobile equipment used for cargo handling and material mobilisation.

At the onshore logistics base, emissions will be generated by diesel-powered equipment such as cranes, forklifts and trucks operating within the existing port environment. No major construction works, dredging, excavation or land reclamation are required, and consequently dust generation is expected to be negligible.

The consequences on air quality will be short-term and spatially limited due to the short period of these activities, the utilization of existing infrastructure, and the lack of construction, dredging, or earthworks. Dust generation is expected to be negligible.

In summary, with regard to their significance, the impacts on air quality during the mobilisation phase are assessed as negative (-), with intensity ranging from negligible to low (IN = 1–2), spatial extent from localised to limited (EX = 1–2), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction effects (SI = 1–2), direct (EF = 4), discontinuous in nature (PR = 1–2), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **minor**.

| Impacts on air quality                               |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.6.2 Exploration Drilling Operations Phase

During the exploration drilling operations phase, atmospheric emissions will be dominated by offshore combustion sources, primarily the MODU, support vessels, and helicopter transfers. The main pollutants will include NO<sub>x</sub>, SO<sub>x</sub>, CO, PM and greenhouse gases, arising from fuel combustion in marine engines and auxiliary power systems.

Based on the emissions inventory for the 67-day drilling campaign, total offshore emissions are conservatively estimated at approximately 331.4 tonnes of NO<sub>x</sub>, 17.6 tonnes of CO, 8.4 tonnes of SO<sub>2</sub> and 4.9 tonnes of PM<sub>10</sub>. The offshore atmospheric emissions inventory indicates that the MODU will constitute the dominant source of air emissions during the Project, accounting for approximately 63% of total NO<sub>x</sub> emissions and a similar proportion of SO<sub>2</sub>, CO and particulate matter emissions. This reflects the continuous power demand associated with drilling operations, dynamic positioning and onboard auxiliary systems throughout the 67-day drilling campaign.

Support vessels represent the second most important emission source, contributing approximately 36% of total offshore emissions. These emissions are associated with routine supply, standby and logistics operations required to support the drilling programme. Although support vessel activity will be intermittent, their cumulative fuel consumption over the drilling campaign results in a significant contribution to the overall emissions inventory.

Helicopter operations will contribute only a minor proportion of total atmospheric emissions (less than 1% for all pollutants), owing to the relatively low fuel consumption and limited frequency of personnel transfer flights.

Overall, the offshore emissions profile is therefore strongly dominated by the operation of the MODU, followed by support vessels, while helicopter activities make a negligible contribution. The absence of planned well testing, venting or flaring further limits the overall atmospheric emissions associated with the Project, such that emissions are almost exclusively related to fuel combustion for power generation, marine transport and logistics support.

No well testing, venting or flaring is planned as part of the drilling programme; therefore, emissions associated with hydrocarbon release or combustion under such conditions are excluded. The contribution to coastal and regional air quality is expected to be negligible due to the drilling site's offshore location (>44 km from shore), favorable dispersion conditions, and absence of sensitive receptors in proximity to the drilling location.

No other offshore drilling activities are planned near the MODU. A screening-level assessment indicates that the Project's contribution of NO<sub>x</sub>, SO<sub>x</sub> and particulate matter to regional background concentrations, including emissions from shipping and other sources in the Ionian Sea, is expected to be negligible. Considering the offshore location, temporary 67-day duration, low sulphur fuel requirement applicable under the Mediterranean SO<sub>x</sub> ECA, and effective atmospheric dispersion, the Project is not expected to cause a significant adverse effect on regional or coastal air quality.

The atmospheric emissions associated with onshore activities at the Port of Igoumenitsa are expected to be minor in comparison with offshore emissions and will represent only a very small contribution to the overall Project emissions inventory. Onshore emissions will arise primarily from the intermittent operation of diesel-powered cargo-handling and logistics equipment, including forklifts, cranes, trucks and other mobile machinery used for loading, unloading, storage and transfer of materials, equipment and wastes within the temporary Supply Base.

Based on the estimated fuel consumption, total emissions from shore base activities over the entire 67-day drilling campaign are estimated at approximately 642 kg of NO<sub>x</sub>, 212 kg of CO, 66 kg of NMVOCs and 41 kg of PM<sub>10</sub>. These quantities are several orders of magnitude lower than the corresponding offshore emissions, reflecting the limited scale and intermittent nature of port-based support activities.

The temporary Supply Base will be established within an existing operational port area where similar cargo-handling and vehicle movements routinely occur. Overall, onshore atmospheric emissions are expected to be localised, temporary and readily manageable through standard good industry practice, including routine equipment maintenance, efficient logistics planning and minimisation of unnecessary vehicle movements and engine idling. Furthermore, the use of ultra-low sulphur diesel in accordance with EU fuel quality standards will minimise SO<sub>2</sub> emissions. As a result, Project-related onshore activities are not expected to result in significant adverse effects on local ambient air quality.

Management measures will focus on fuel consumption, engine efficiency, logistics optimisation, compliance with MARPOL Annex VI fuel sulphur requirements, and the identification and reporting of any methane releases that may arise from in-scope exploration activities.

In summary, with regard to their significance, the impacts on air quality during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN=1-2), localised to the onshore port area and extending to the offshore operational area (EX=1-2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing marine and port emissions (SI=2), direct (EF=4), either continuous or occasional depending on the activity (PR=1-4), with short-term recovery after completion of drilling (MC=1-2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

| Impacts on air quality                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

| Helicopter transfers between heliport and MODU          | -          | 1              | 2           | 4           | 1                | 1                  | 2            | 4           | 1                | 1             | 1                 | 22                    | Low        | Medium                     | MINOR               |

#### 10.1.6.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, atmospheric emissions will arise primarily from the departure and transit of the MODU and support vessels from the drilling location, helicopter transfers (if required), and the dismantling and removal of temporary facilities, equipment and materials from the onshore logistics base at the Port of Igoumenitsa.

Offshore emissions will mainly originate from fuel combustion associated with vessel transit and well abandonment activities, including MODU operation and surface handling operations. The principal pollutants emitted will include nitrogen oxides (NO<sub>x</sub>), sulphur oxides (SO<sub>x</sub>), carbon monoxide (CO), particulate matter (PM) and greenhouse gases (GHGs). However, as these activities are of relatively short duration compared to the overall drilling campaign, atmospheric emissions are expected to be lower than those generated during active drilling operations.

Onshore emissions will result from the use of trucks, cranes, forklifts and other mobile equipment required for the removal and transport of temporary installations, drilling materials and waste from the Supply Base. As all activities will take place within an existing operational port area and no demolition, excavation or earthworks are planned, dust generation is expected to be negligible.

Overall, atmospheric emissions during demobilisation and abandonment will be temporary, localised and operational in nature, due to the short duration of the activities, the use of existing infrastructure, compliance with applicable international and European emission standards, and the absence of major construction works.

In summary, with regard to their significance, the impacts expected on air quality during the demobilisation and abandonment phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=2), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), synergistic (SI=2), direct (EF=4), discontinuous (PR=1), of short-term recovery (MC=2), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **minor**.

| Impacts on air quality                           |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

## 10.1.7 Impacts on the acoustic environment and emissions of vibrations and radiation

### 10.1.7.1 Airborne noise

#### 10.1.7.1.1 Drilling preparation and mobilisation phase

**Offshore**, the principal noise sources will comprise the transit of the MODU to the drilling location, support and supply vessel movements, operation of vessel propulsion systems, auxiliary engines, generators and deck machinery during positioning, loading operations and commissioning activities. These noise emissions will be temporary, and their effect will be predominantly in the offshore operational area. Considering the well site's remote location, approximately 44 km from the nearest shoreline, airborne noise generated offshore will not be perceptible at onshore noise-sensitive receptors.

Offshore noise will primarily affect personnel onboard the MODU and vessels, with occupational exposure managed through the relevant MODU and vessel operators' management systems, supported by Energean's contractor assurance arrangements, and applicable maritime regulations.

**Onshore**, noise will be associated with unloading and storage of equipment at the Port of Igoumenitsa shore base, forklift and crane operations, heavy goods vehicle movements, installation of temporary offices and utilities, and routine logistics activities.

These activities will occur within an existing commercial port environment where elevated background noise levels are already present due to port operations and traffic. The number of personnel involved will be limited and the activities will be temporary. Consequently, only negligible short-term increases in ambient noise levels are expected at nearby receptors, with no significant disturbance anticipated.

In summary, with regard to their significance, airborne noise impacts during the mobilisation phase are assessed as negative (-), with intensity ranging from negligible to low (IN = 1-2), spatial extent from localised to limited (EX = 1-2), occurring immediately during mobilisation activities (MO = 4), coincident with the

mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction effects (SI = 1–2), direct (EF = 4), discontinuous in nature (PR = 1–2), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **minor**.

| Airborne noise impacts                               |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.7.1.2 Exploration drilling operations phase

During drilling operations, the MODU will represent the main source of airborne noise throughout the 67-day drilling campaign. Continuous operation of main engines, diesel generators, DP system and thrusters, drilling machinery, mud pumps, ventilation systems, compressors and other auxiliary equipment will generate continuous airborne noise within the immediate vicinity of the drilling unit. Additional intermittent noise will arise from deck equipment operation (e.g. cranes), pipe handling, supply vessel loading and unloading, bulk material transfers, waste handling activities and routine maintenance operations.

Support and supply vessels undertaking crew transfers and logistical support will also contribute periodic airborne noise through engine operation and manoeuvring.

Helicopter transfers between Corfu International Airport and the MODU will generate short-duration airborne noise during take-off, landing and overflight. Flights are expected to occur only several times per week and will generally follow routes determined by the aviation operator in accordance with applicable aviation requirements, operational safety and relevant noise-abatement procedures. Considering the MODU's offshore position and the limited frequency and duration of helicopter operations, helicopter noise is not expected to result in significant disturbance to onshore receptors.

Because the MODU is located approximately 44 km offshore, atmospheric attenuation over this distance will substantially reduce airborne noise propagation, and noise generated by offshore operations is not expected to be perceptible at the nearest island or mainland communities. Consequently, no significant impacts on terrestrial noise-sensitive receptors are anticipated.

Onshore, airborne noise will arise from continued logistics activities at the Port of Igoumenitsa shore base, including loading and unloading of supplies, waste handling, forklift and crane operations, vehicle movements and routine administration. These activities will occur within an established industrial port environment, where similar noise sources already exist. The small onshore workforce and relatively low intensity of shore base operations mean that any increase in ambient noise levels will be minor and temporary, without materially affecting nearby receptors.

In summary, with regard to their significance, airborne noise impacts during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN=1-2), localised to the onshore port area and extending to the offshore operational area (EX=1-2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing noise emissions (SI= 1 - 2), direct (EF=4), either continuous or occasional depending on the activity (PR=1-4), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

### 10.1.7.1.3 Demobilisation and abandonment phase

During demobilisation and abandonment, airborne noise levels will progressively decrease as drilling activities cease and equipment is removed from the well site. Offshore noise sources will include cement plug installation, well abandonment operations, retrieval of subsea equipment, MODU circulation and final well handling activities, crane operations, loading of equipment onto support vessels, vessel manoeuvring and the departure of the MODU from the operational area. These activities will be temporary and of shorter duration than the drilling phase.

The offshore location of the Project ensures that airborne noise generated during abandonment and demobilisation will not be perceptible at onshore noise-sensitive receptors. Occupational exposure onboard the MODU and support vessels will continue to be managed through the relevant MODU and vessel operators' health and safety procedures and applicable regulatory requirements.

Onshore, noise will be generated by the transfer of equipment and materials to the shore base at the Port of Igoumenitsa, unloading activities, dismantling of temporary facilities, waste transfer operations and increased heavy vehicle movements associated with demobilisation. These activities will occur over a relatively short period within the existing operational area of the port and will utilise existing transport routes. Following completion of demobilisation, all temporary activities will cease, and ambient noise levels will return to baseline conditions.

In summary, with regard to their significance, airborne noise impacts during the demobilisation and abandonment phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=1 – 2), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), with limited synergistic effects with existing port noise emissions (SI= 1 – 2), direct (EF=4), discontinuous (PR=1), of short-term recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **minor**.

#### 10.1.7.2 Underwater noise

The underwater acoustic environment of the Project area is shaped by both natural and anthropogenic sound sources. Natural sources include wind, waves, rainfall, seismic activity and biological sounds produced by marine mammals, fish and other marine organisms. Anthropogenic sources include commercial shipping, fishing vessels, sonar systems, military activities and offshore exploration activities. Underwater sound levels are expressed in dB re 1 µPa and are not directly comparable with airborne sound levels, which use a different reference pressure. For continuous underwater noise, root mean Square Sound Pressure (SPLrms) is commonly used, while peak sound pressure (SPLpeak) is more relevant for impulsive or transient sound sources.

Baseline acoustic monitoring undertaken in the Ionian Sea indicates that the existing soundscape is already influenced by vessel traffic and intermittent anthropogenic noise events. During the April 2026 offshore monitoring campaign, daily percentile levels were calculated for the 63 Hz and 125 Hz third-octave bands. The average L90 SPLrms value was approximately 89.8 dB re 1 µPa at 63 Hz and 85.6 dB re 1 µPa at 125 Hz, while the corresponding average L90 SPLpeak values were approximately 100.5 dB re 1 µPa and 96.8 dB re 1 µPa respectively. These values indicate a moderately disturbed offshore soundscape influenced mainly by distant vessel noise, particularly low-frequency propeller cavitation and shipping activity.

The monitoring results also showed intermittent anthropogenic noise events, including probable airgun signals, explosive-type sounds and high-frequency active sonar. These findings indicate that the Project area is already subject to variable natural and human-generated underwater noise. Previous monitoring in the wider Ionian Sea also recorded elevated peak sound pressure levels in coastal and semi-enclosed areas, with the North Ionian showing average SPLpeak values of approximately 127.1 dB re 1 µPa. However, the Project-specific offshore measurements were lower than those recorded in more traffic-influenced coastal waters.

An underwater noise impact study was conducted for the Asopus-1 exploration drilling campaign. The study characterises impulsive sound from the impulsive VSP airgun array and non-impulsive sound from the drillship, including dynamic positioning operations, and from associated Project vessels. It models underwater sound propagation under representative seasonal conditions and estimates the distances at which the adopted acoustic effect criteria may be reached for marine mammals, fish and sea turtles.

This study comprises the following:

- an overview of the underwater acoustic terminology and metrics used in the assessment;
- characterisation of impulsive sound from the VSP airgun array and non-impulsive sound from the drillship and associated Project vessels;
- identification of relevant marine-fauna receptors and acoustic effect criteria;
- a description of the underwater sound propagation modelling methodology and input data;
- presentation and interpretation of the propagation and acoustic-effect modelling results; and
- a review of the principal assumptions and limitations of the assessment.

The principal sources of underwater noise are vessel movements during mobilisation and demobilisation, operational sound from the dynamically positioned drillship during drilling, and impulsive sound from the VSP airgun array, if VSP acquisition is undertaken during the drilling phase. The modelled distances represent conservative screening thresholds and should not be interpreted as continuous ecological impact areas.

The underwater sound modelling estimated the maximum distances at which adopted acoustic screening levels may be reached. These distances are conservative modelled threshold ranges and should not be interpreted as continuous impact areas.

#### 10.1.7.2.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, underwater noise will be generated mainly by the transit and positioning of the MODU and support vessels. The principal noise sources will be vessel propulsion, propeller cavitation, auxiliary machinery and, during final positioning, dynamic positioning systems. These sources are similar in character to existing vessel noise already present in the Ionian Sea acoustic environment.

No drilling, VSP operations or wellhead activities will occur during mobilisation. Therefore, underwater noise during this phase will be limited to short-term vessel movements and marine logistics. Helicopter transfers, where undertaken, are expected to make a negligible contribution to underwater noise because air-to-water acoustic coupling is weak and any underwater sound is short-lived and confined to the area directly below the aircraft.

Representative literature values indicate that support vessels may generate underwater source levels of approximately 180–190 dB re 1  $\mu$ Pa @ 1 m, mainly in the low-frequency range, while small to medium offshore vessels may fall within the broader range of 170–195 dB re 1  $\mu$ Pa @ 1 m depending on vessel type, propulsion system, speed and loading condition.

In the context of the measured baseline soundscape, mobilisation underwater noise will represent a temporary increase above existing vessel-related background noise. At 14 knots, the maximum modelled

distance to the lower adopted screening level is approximately 54 km for the conservatively modelled support-vessel source. For the drillship in transit, the corresponding distances are approximately 33.7 km. At 4 knots, the modelled distance is substantially lower, approximately 9.9 km, depending on vessel type.

These results indicate that underwater sound from mobilisation may propagate over comparatively large distances under conservative conditions, particularly during open-water transit. However, vessel transit is temporary, mobile and limited in duration.

In summary, with regard to their significance, underwater noise impacts during the mobilisation phase are assessed as negative (-), of low intensity (IN = 2), limited spatial extent (EX = 2), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**

| Underwater noise impacts                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |                                  |

#### 10.1.7.2.2 Exploration Drilling Operations Phase

During the exploration drilling phase, the dominant continuous underwater noise source will be the MODU operating at the well location. Main contributors will include dynamic positioning thrusters, propulsion systems, onboard machinery, power generation systems, drilling-related equipment and structure-borne vibration. Drilling and onboard equipment noise is expected to be dominated by low-frequency components.

Support vessels will generate additional intermittent underwater noise during supply, standby and logistics operations. Vessel noise will mainly arise from propulsion, propeller cavitation, vessel manoeuvring and auxiliary machinery.

Representative literature values indicate a drillship source level of approximately 195 dB re 1  $\mu$ Pa @ 1 m, with a typical frequency range of 40–600 Hz, while support vessels are expected to generate approximately 180–190 dB re 1  $\mu$ Pa @ 1 m within the 50–300 Hz range.

Compared with the baseline acoustic conditions recorded in April 2026, the drillship and support vessels will introduce a continuous localised source of low-frequency underwater noise at the well location. This may temporarily increase the local sound field above background levels, particularly in the vicinity of the MODU. However, the measured baseline already shows influence from distant shipping and intermittent anthropogenic events, and the Project source is temporary and spatially restricted. Conceptual modelling for comparable deepwater offshore drilling activities indicates that underwater noise from drilling and vessel operations attenuates rapidly with distance from the source.

During VSP operations, impulsive sound energy is transmitted from a near surface source to receivers located within the wellbore. The emitted sound energy is predominantly directed towards the seabed and subsurface geological formations, with the highest sound levels occurring immediately beneath the source. Each air gun discharge also ensonifies the surrounding water column, generating a short-duration, low-frequency impulse whose received level decreases with increasing distance from the source. VSP will involve short-duration airgun pulses from a small source deployed from the drillship, and will be substantially lower in total acoustic output, duration and spatial extent than conventional 2D or 3D seismic surveys. The activity is expected to involve a limited number of shots over short operational periods at a single well location.

If VSP acquisition is undertaken, the VSP airgun array will represent the highest-energy underwater sound source during the drilling phase. For a single VSP discharge, higher-level acoustic screening distances are generally limited to the immediate vicinity of the source, mostly at or below approximately 151 m, with a maximum reported distance of approximately 302 m. Lower-level screening distances are larger, reaching up to approximately 12.6 km for one screening criterion, and up to approximately 40.1 km for another lower screening criterion.

While each VSP wireline logging operation is allocated a 12-hour survey window on the rig schedule for tool deployment, depth positioning, testing, and retrieval, the actual active airgun discharge is expected to comprise approximately ~130 shots per section (~260 shots total across the entire campaign) at 15-second firing intervals. This results in an active firing duration of only ~97.5 minutes per section (~3.3 hour total cumulative firing across the campaign).

Routine drilling noise is continuous rather than impulsive, and the highest exposure levels will be limited to the area close to the MODU and support vessels. For drillship operational sound, near-source screening distances are short, generally around 31 m and limited by model resolution. The lower adopted screening level is reached at approximately 29 km. For cumulative exposure, the conservative 24-hour fixed-receptor scenario gives a maximum modelled distance of approximately 21.5 km for the most sensitive cumulative screening case. This result assumes a stationary receptor and continuous operation at the modelled source level; actual sound exposure will vary with drillship operating mode, dynamic-positioning thruster demand and local conditions.

With regard to the impacts from drilling contingency activities, extended drilling, re-spudding, sidetracking, vessel activity, ROV operations, well suspension, reconnection and pipe recovery could increase the duration of underwater noise emissions. The use of an explosive pipe-severance device, if required in a stuck pipe contingent case, could generate a very short-duration localised underwater noise and vibration event deep into the wellbore and within the drill string. These impacts would be temporary and localised. They may increase short-term disturbance to marine fauna in the vicinity of the MODU but would not introduce a continuous or long-term underwater noise source beyond the drilling campaign.

In summary, with regard to their significance, underwater noise impacts during the drilling operations phase are assessed as negative (-), of varying intensity depending on the activity (IN = 1 – 4), extending to the offshore operational area (EX = 1 – 2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing noise emissions (SI= 1 – 2), direct (EF=4), either continuous or occasional depending on the activity (PR=1–4), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **moderate**.

Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

### 10.1.7.2.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, underwater noise will arise mainly from well plug and abandonment activities, continued MODU operation, support vessel movements, ROV inspection and final vessel departure from the well location. The principal noise sources will remain the non-impulsive vessel propulsion, dynamic positioning thrusters, onboard machinery, generators, pumps and short-term subsea inspection activities.

Plug and abandonment activities will be carried out from the MODU using conventional well control, cementing and circulation systems. These activities are not expected to introduce a materially different underwater noise source from those already generated during routine MODU and vessel operations.

As abandonment progresses, Project-related underwater noise will gradually reduce. Once plug and abandonment activities are completed and the MODU and support vessels depart, Project-related underwater noise will cease and the local acoustic environment is expected to return to baseline conditions.

In the context of the existing variable Ionian Sea soundscape, underwater noise effects during demobilisation and abandonment are expected to remain limited in duration and spatial extent. The activities will be temporary, localised and reversible, with no explosive sources, pile driving, large-scale seismic surveys or wellhead cutting involved.

In summary, with regard to their significance, underwater noise impacts during the demobilisation and abandonment phase are assessed as negative (-), of low intensity (IN= 1 – 2), localised (EX=1 – 2),

immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), with limited synergistic effects with other activities (SI= 1 – 2), direct (EF=4), discontinuous (PR=1), of short-term recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **moderate**.

Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

### 10.1.7.3 Vibrations

#### 10.1.7.3.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, offshore vibration sources will be associated mainly with the mobilisation, movement and positioning of the drillship and support vessels. These may include propulsion systems, engines, generators, auxiliary machinery and vessel manoeuvring systems.

Project vessels may operate at approximately 14 knots during open-water transit and at approximately 4 knots during lower-speed movement near the Project area. The maximum anticipated sailing time for Project vessels is approximately seven hours. As these are moving sources, vibration exposure at any single location will be short-term and will reduce as the vessel moves away.

The drillship will be dynamically positioned and no anchoring will be undertaken. Therefore, no anchor handling, anchor drag or mooring-related seabed vibration is expected. No seabed preparation, dredging or construction works are planned during mobilisation.

At the onshore support base, vibration sources during this phase may include mobilisation logistics, loading and unloading of supplies, movement of trucks and forklifts, crane operations, temporary storage and handling of materials, and vessel berthing or departure. These activities will take place within an existing port environment and will be comparable to routine port operations. No works capable of generating significant ground-borne vibration are planned.

In summary, with regard to their significance, vibration impacts during the mobilisation phase are assessed as negative (-), of negligible to low intensity (IN = 1-2), limited spatial extent (EX = 1-2), occurring immediately

during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with none to moderate synergistic interaction effects (SI = 1-2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by immediate recovery potential (MC = 1), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Vibration Impacts                                    |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.7.3.2 Exploration drilling operations phase

During exploration drilling operations, offshore vibrations may be generated by the drillship's engines, generators, pumps, drilling equipment and dynamic-positioning thrusters. These sources will operate depending on the drilling activity and the level of thruster demand required to maintain the drillship's position.

Vibrations may be transmitted through the drillship structure, marine riser, subsea equipment and wellbore. However, such effects are expected to remain localised around the drillship and well location. Direct drill-bit vibration is expected to be confined to the wellbore and immediately surrounding formation and is not expected to generate seabed-wide or regional vibration effects.

If VSP acquisition is undertaken, it would represent a short-duration impulsive vibration source in the water column. The activity would not be continuous throughout the drilling campaign and is expected to comprise discrete acquisition sequences at approximately 230 stations in total. VSP-related vibration would cease immediately after completion of the acquisition activity and would not involve physical disturbance of the seabed.

At the onshore support base, vibration sources during the exploration drilling operations phase would be limited to intermittent logistics and support activities, including support-vessel turnaround, loading and unloading of consumables, waste transfer, truck movements and handling of materials. These activities would be temporary, intermittent and within the normal operational context of the port.

In summary, with regard to their significance, vibration impacts during the drilling operations phase are assessed as negative (-), of negligible to moderate intensity (IN=1–4), localised or extending to the offshore operational area depending on the activity (EX=1–2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects (SI= 1 – 2), direct (EF=4), occasional (PR=1), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

### 10.1.7.3.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, offshore vibration sources will be associated with well abandonment activities, operation of onboard equipment, dynamic positioning, support vessel movements and the departure of the drillship from the Project area.

Plugging and abandonment activities may involve pumps, cementing equipment and other onboard systems, but these are not expected to generate significant vibration beyond the immediate wellbore and drillship area. No piling, blasting, anchoring, seabed excavation or construction works are planned as part of abandonment.

Support vessel and drillship movements during demobilisation will generate temporary vessel-related vibrations similar to those during mobilisation. These will be short-term and associated with moving vessels. Exposure at any one location will therefore be limited in duration.

At the onshore support base, vibration sources during demobilisation may include unloading and backloading of equipment, waste transfer, truck movements, forklift and crane operations, temporary materials handling and vessel berthing or departure. These activities will occur within an existing port setting and are not expected to generate vibration levels materially different from routine port operations.

In summary, with regard to their significance, vibration impacts during the demobilisation and abandonment phase are assessed as negative (-), of low intensity (IN=2), within the Project footprint (EX=1), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), with no synergistic effects (SI= 1), direct (EF=4), discontinuous (PR=1), of short-term recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

#### 10.1.7.4 Electromagnetic radiation

##### 10.1.7.4.1 Drilling preparation and mobilisation phase

No radioactive sources or equipment generating significant electromagnetic radiation will be used during mobilisation activities. Electromagnetic emissions will be limited to routine operation of marine navigation, communication and positioning systems onboard the MODU, support vessels and helicopter, together with standard communication equipment at the shore base. These systems operate within internationally regulated frequency bands and represent normal maritime operations. Consequently, no significant impacts associated with electromagnetic radiation or radioactivity emissions are anticipated during mobilisation.

In summary, with regard to their significance, radiation impacts during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), non-synergistic (SI = 1), direct (EF = 4), discontinuous (PR = 1), restored immediately (MC = 1), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Radiation impacts                                    |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

##### 10.1.7.4.2 Exploration drilling operations phase

During drilling operations, electromagnetic radiation will be generated by the routine operation of navigation, communication and positioning systems onboard the MODU, support vessels and helicopters. These include marine radar, satellite communications, Global Positioning System (GPS), Automatic Identification System (AIS), Very High Frequency (VHF) and Ultra High Frequency (UHF) radio systems, and dynamic positioning (DP) reference systems. These systems operate continuously throughout the drilling campaign but are designed and operated in accordance with applicable international telecommunications and occupational

exposure standards. Their operation is comparable to that of other commercial offshore vessels and is not expected to measurably alter the existing electromagnetic environment.

Sealed radioactive sources may be used intermittently during logging-while-drilling (LWD) and wireline logging operations for formation evaluation. These sources are fully encapsulated within specialised downhole logging tools and remain contained throughout deployment. They are retrieved following completion of each logging operation and are managed under strict radiation protection procedures in accordance with applicable international standards, European Union legislation and Greek radiation protection regulations. No discharge or release of radioactive material to the marine environment is planned, and no exposure of the public or the environment is expected during normal operations.

No Naturally Occurring Radioactive Material (NORM) associated with produced fluids is anticipated during the exploration drilling programme. Consequently, no radioactive wastes or NORM-contaminated materials requiring management are expected to be generated.

Overall, electromagnetic radiation and the temporary use of sealed radioactive sources are not expected to result in measurable impacts on the environment or nearby receptors.

In summary, with regard to their significance, radiation impacts during the drilling operations phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=1), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with no synergistic effects (SI= 1), direct (EF=4), occasional (PR=1), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Radioactive source use and storage (well logging)           | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20                    | Negligible | Low                        | NEGLIGIBLE          |
| Onshore storage and transport of radioactive sealed sources | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20                    | Negligible | Low                        | NEGLIGIBLE          |

#### 10.1.7.4.3 Demobilisation and abandonment phase

During demobilisation and well abandonment, electromagnetic emissions will progressively decrease as drilling activities cease and the MODU, support vessels and associated equipment are removed from the operational area. Remaining emissions will be limited to routine marine communication, navigation and positioning systems used during vessel transit and equipment retrieval.

Any sealed radioactive sources used during drilling operations will have been recovered upon completion of logging activities and removed from the MODU by the specialist service contractor, in accordance with applicable radiation protection requirements. No radioactive materials will remain on the seabed or within the abandoned well, and no radioactive discharges or emissions will occur during demobilisation.

Following completion of the Project, all temporary sources of electromagnetic radiation associated with offshore operations will cease, and no residual impacts related to electromagnetic radiation or radioactivity emissions are anticipated.

In summary, with regard to their significance, radiation impacts during the demobilisation and abandonment phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=1), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), with no synergistic effects (SI=1), direct (EF=4), discontinuous (PR=1), of short-term recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

## 10.1.8 Impacts on Water Resources

### 10.1.8.1 Seawater quality

#### 10.1.8.1.1.1 Drilling preparation and mobilisation phase

With regard to the mobilisation phase, the principal pathway for impacts to seawater quality is associated with the transit of the MODU and associated support vessels to the well location. During mobilisation, power generation required for vessel propulsion and onboard operations, together with routine vessel activities (including discharge of sanitary, food and desalination units), has the potential to result in minor and temporary changes to seawater quality.

The mobilisation route will occur within an existing maritime environment that already experiences regular commercial shipping traffic. Consequently, the MODU and associated support vessels will represent only a minor and temporary increase in vessel presence relative to baseline conditions. Any routine discharges associated with power generation, and vessel movements are expected to comply with applicable national and international maritime regulations and industry standards.

No suspended sediment related disturbance is anticipated during mobilisation, as drilling activities and other seabed-interacting operations will not yet have commenced. Therefore, increases in suspended sediment concentrations are not predicted during this phase. Unlike shallow-water drilling projects where anchoring may be required, the proposed MODU will maintain station using dynamic positioning. As a result, no seabed disturbance associated with anchor placement or anchor line drag is anticipated.

Embedded mitigation measures, including vessel maintenance procedures, adherence to pollution prevention requirements, and implementation of spill response arrangements, will minimise the likelihood of releases during loading, unloading and transit activities. In the event of a minor release, the open-water

environment and relatively high dilution capacity of the receiving waters would be expected to limit the duration and magnitude of water quality effects.

In summary, with regard to their significance, the impacts expected on seawater quality during the mobilisation phase are assessed as negative (-), of negligible intensity (IN=1), within the local area (EX=2), occurring immediately during mobilisation activities (MO = 4), coincident with mobilisation activities (PE=1), short-term reversible (RV=1), non-synergistic (SI=1), direct (EF=4), discontinuous (PR=1), immediately restored (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

| Impacts on Seawater Quality                          |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |                              |

#### 10.1.8.1.1.2 Exploration drilling operations phase

Within the exploration drilling and operations phase, impacts to seawater quality may arise through sediment resuspension from localised seabed disturbance and planned operational discharges to the marine environment. The principal impact pathways are therefore increased suspended sediment concentrations, temporary changes in water quality parameters, and the addition of drilling-related discharges to the receiving environment.

The proposed MODU will maintain station using dynamic positioning. As a result, no seabed disturbance associated with anchor placement or anchor line drag is anticipated. Seabed disturbance will therefore be restricted principally to activities directly associated with drilling infrastructure installation and operation.

Water circulation in the region is strongly influenced by broader Mediterranean oceanographic processes, including the circulation patterns of the Ionian Sea and exchanges between the Adriatic and Eastern Mediterranean basins. These processes promote the dispersion and dilution of suspended material and dissolved constituents introduced into the marine environment. The proposed well location is situated within offshore waters of the Eastern Ionian Sea, an area generally characterised by oligotrophic (low productivity) conditions, high water clarity, and relatively low levels of anthropogenic contamination (Annex 02, ESBS).

Temporary seabed disturbance will occur during drilling, including the well construction and temporary placement of subsea equipment associated with the drilling operation. These activities will result in the localised disturbance of seabed sediments and subsequent increases in suspended sediment concentration within the immediate vicinity of the well location. Sediment particles released into the water column are anticipated to disperse and settle progressively with increasing distance from the source. Consequently, high concentrations of suspended sediment are expected to decrease rapidly away from the drill site. The nature of resuspended material will be influenced by local seabed sediment characteristics. In deeper areas of the Eastern Ionian Sea, sediments are typically dominated by fine-grained silts and clays (see Section 8.3.2),

which may remain suspended within the water column for longer periods than coarser sediments following disturbance. Nevertheless, prevailing hydrodynamic conditions are expected to facilitate dispersal whilst limiting significant accumulation beyond the immediate vicinity of the disturbance source. Following completion of the relevant activities, suspended sediments are expected to settle naturally, resulting in progressive recovery of baseline water quality conditions.

Planned discharges during drilling operations (see Sections 6.8 and 6.9) may include riserless drilling fluids and cuttings, riser drilling discharges, cement returns, ballast water, cooling water, deck drainage, wastewater and blowout preventer fluids. These discharges have the potential to temporarily affect water quality characteristics including turbidity, suspended solids concentrations, dissolved oxygen levels and concentrations of certain chemical constituents within localised areas surrounding the well.

Drill cuttings dispersion modelling predicts that suspended material may be transported away from the discharge location under the influence of prevailing currents, with plume extent varying according to seasonal oceanographic conditions. Drilling discharges may cause temporary changes to seawater quality through the dispersion of drilling fluids, cuttings and associated chemicals. The modelling was based on conservative, worst-case assumptions, including contingency materials (barite/bentonite) that are not expected to be used routinely. Screening-threshold exceedances were predicted mainly near the well location seabed during riserless discharges and in the upper water column during riser discharges.

For the physical presence of suspended drill cuttings in the water column, a PNEC of 100,000 ppb, equivalent to 100 mg/L, has been applied as a screening threshold within the ERMS/DREAM risk-assessment framework (described in Section 6.9.1.1.6). This threshold relates to potential physical effects from suspended particulate matter, such as increased turbidity and particle exposure, rather than chemical toxicity. Exceedance of the threshold would indicate a potential for short-term physical stress to water-column receptors and the need for further assessment; it does not by itself demonstrate confirmed ecological harm. Concentrations of this magnitude, if they occur, would be expected to be confined to the immediate near field of the discharge point, where dilution has not yet substantially reduced suspended solids concentrations. As a conservative broad estimate, any exceedance of the 100,000 ppb suspended-cuttings threshold would be expected to remain within approximately 0.1–0.5 km of the discharge location, and unlikely to extend beyond about 1 km. During riserless sections, this would occur close to the seabed around the well, while during riser sections it would occur close to the sea-surface discharge point before dilution, dispersion and settling through the water column.

Concentrations decrease rapidly with increasing distance from the source point; therefore highest concentrations are confined to the immediate source vicinity of the well while lower levels of concentration are predicted at the outer margins of the plume. Model predictions indicate a greater extent of dispersion during periods of stronger current activity. However, environmental risk associated with suspended material in the water column is predicted to be temporary, with concentrations declining rapidly following cessation of discharges due to natural dilution and dispersion processes. The Mediterranean offshore environment is characterised by substantial water depths and open-water circulation, which promote rapid dilution of discharged materials. Consequently, elevated concentrations of suspended solids and other discharge-related constituents are expected to remain localised and temporary.

Baseline data indicate that offshore sediments within the project area are generally uncontaminated. Whilst isolated exceedances of Pb and Ni were recorded; these showed no relationship with the proposed well

locations and are considered more likely to reflect natural geochemical variability than anthropogenic contamination. Subsequently, sediment resuspension is not expected to result in a significant release of contaminants to the water column or measurable degradation of seawater quality.

Routine operational discharges from the MODU and associated support vessels, including sanitary waste, food waste, desalination unit discharges, drainage water and cooling water have potential to affect concentrations of suspended solids, nutrients and chlorine, as well as to generate biological oxygen demand (BOD). However, these impacts are expected to be localised and temporary, with natural dilution and dispersion processes within the open marine environment limiting the extent and duration of any effects on seawater quality. Furthermore, discharges will be treated in line with best practice and legislative requirements, including those associated with MARPOL Annex V, Mediterranean Sea Special Area provisions and MARPOL Annex IV (sewage).

With regard to the impacts from drilling contingency activities, re-spudding and sidetracking may increase the volume of water-based drilling fluids, cuttings and cement associated with the drilling programme. An Emergency Disconnect Sequence may result in localised discharge of riser contents, including drilling fluids or cuttings, at the seabed. Lost-circulation response may require additional use of loss circulation material and cement, although fluids lost to the formation would not normally be discharged to the marine environment. Potential impacts include localised turbidity, increased suspended solids, short-term changes in water quality near the discharge location, and physical deposition of drilling residues or cement. These effects would be temporary and localised, with dilution and dispersion occurring in the offshore marine environment.

Overall, impacts on seawater quality from drilling discharges are expected to remain localised, temporary and reversible. The highest suspended-solid concentrations would occur only in the immediate near-field of the discharge points, with any potential exceedance of the 100 ppm suspended-cuttings screening threshold unlikely to extend beyond 1 km. Concentrations are expected to decrease rapidly with distance due to dilution, dispersion and particle settling, and elevated levels are not predicted to persist after discharges cease. Considering the offshore location of the well, approximately 44.3 km from the nearest Greek land, these effects would not reach the shoreline or cause measurable degradation of coastal seawater quality under the assessed drilling-discharge scenarios.

In summary, with regard to their significance, impacts expected on seawater quality during the operational exploration phase are assessed as negative (-), ranging from negligible to moderate (IN=1-4), within the project footprint to local (EX=1-2), immediate (MO=4), temporary or permanent throughout the drilling period, depending on the activity (PE=1-4), short-term to medium-term reversible (RV=1-2), synergistic (SI=2), direct (EF=4), irregular or continuous (PR=1-4), with immediate to medium-term restoration (MC=1-3), and cumulative (AC=4). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

#### 10.1.8.1.1.3 Demobilisation and abandonment phase

For the demobilisation and well abandonment phase, the principal pathways for impacts to seawater quality are associated with MODU circulation and surface handling operations, and the removal of temporary subsea infrastructure. These activities have the potential to result in localised and temporary changes to seawater quality through the disturbance of suspended sediments and operational discharges associated with MODU circulation.

Impacts are expected to be largely confined to the immediate vicinity of the well location and will occur over a relatively short duration. Wellbore contents and fluids are to be displaced and circulated before being discharged to the sea under controlled conditions in accordance with operational procedures. The discharges include weighted drilling mud, cement contaminated mud, water, barite, and cement polymers. A further discharge of up to 1,312 tonnes of drilling fluid may be conducted during the well plug and abandonment process. These discharges are expected to be localised and settle on the seabed near the well site, with natural dilution and dispersion processes within the open marine environment assisting recovery following the completion of activities.

MODU circulation and surface handling operations may result in discharges to the marine environment; however, embedded mitigation measures, including adherence to discharge management procedures, pollution prevention requirements and operational controls, will minimise the likelihood and magnitude of adverse effects on seawater quality.

The removal of temporary subsea infrastructure may also generate short-term and localised seabed disturbance, although effects are anticipated to be limited in extent.

In summary, with regard to their significance, impacts expected on seawater quality during the demobilisation and well abandonment phase are assessed as negative (-), of negligible intensity (IN=1), within the project footprint (EX=1), immediate (MO=4), temporary (PE=1), short-term reversible (RV=1), synergistic (SI=2), direct (EF=4), irregular (PR=1), with short-term restoration (MC=2), and cumulative (AC=4). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in Chapter 11 of this ESIA, residual impacts are assessed as **minor**.

## 10.1.8.2 Surface water and groundwater

### 10.1.8.2.1 Drilling preparation and mobilisation phase

During mobilisation, potential impacts on the qualitative and quantitative characteristics of surface water and groundwater are limited to the temporary operation of the shore base within the Port of Igoumenitsa.

No groundwater abstraction, surface water abstraction or wastewater discharges to inland surface waters are planned.

Installation activities may include the placement of temporary equipment and facilities within existing operational areas and connection to existing port services, where required. These works can temporarily

alter surface drainage patterns by introducing compacted operational surfaces, which may change the way rainfall runoff is collected and conveyed within the site. This may slightly alter runoff behaviour during rainfall events, increasing or concentrating surface water flow locally within the shore base footprint. However, any alterations to surface water drainage are expected to be minimal and reversible due to the small area of operations and the fact that the construction takes place within an existing port environment.

With respect to groundwater, the principal consideration is subsurface interaction during any shallow excavation or installation of service trenches, or utility connections. Where shallow digging is required (e.g. for power cables), there is a theoretical potential for localised disturbance of near-surface soils. However, in a port setting such as Igoumenitsa, groundwater is typically already influenced by existing infrastructure and paved operational areas within the port, as well as saline intrusion.

The small onshore workforce will utilise existing or temporary welfare facilities, as appropriate. Associated wastewater will be managed through existing port services or authorised contractors, eliminating any direct discharge to soil, surface water or groundwater. No measurable effects on the quality or availability of surface water or groundwater resources are anticipated from the temporary mobilisation activities, as there will be no wastewater releases.

In summary, with regard to their significance, the impacts on surface water and groundwater during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised spatial extent (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction effects (SI = 1-2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **minor**.

| Impacts on surface water and groundwater          |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.8.2.2 Exploration drilling operations phase

During drilling operations, the Project will not require abstraction of freshwater from local surface water bodies or groundwater resources and therefore will not affect the quantitative status of these water resources. Freshwater requirements for the MODU will be met primarily through onboard desalination systems, eliminating the need for routine abstraction of potable water from onshore water resources. As a contingency measure, provision has been made for the temporary supply of up to approximately 6,000 barrels (approximately 954 m<sup>3</sup>) of potable water from shore facilities in the unlikely event of a prolonged outage of the onboard desalination systems. This represents a one-off contingency requirement rather than

a routine operational demand and is not expected to place a measurable burden on the regional water supply system or affect the quantitative status of local surface water or groundwater resources.

Surface runoff on operational areas such as container yards, waste storage areas and vehicle movement zones will be collected through the existing port stormwater drainage network, and small amounts of hydrocarbons, sediments or other minor operational residues may be present on paved surfaces. However, this pathway is expected to be of limited significance due to the operation of the port drainage system and the application of standard good practice measures, including the use of bunded storage, covered waste containers, spill prevention controls and the separation of clean and potentially operational areas.

Onshore wastewater generation will remain limited to sanitary wastewater from the small shore base workforce, managed through existing or temporary welfare facilities, as appropriate, with wastewater managed through existing port services or authorised contractors, without discharge to the environment.

Offshore wastewater generated onboard the MODU and support vessels will be managed within vessel systems in accordance with MARPOL requirements and discharged offshore under controlled conditions or retained for onshore disposal where required.

Potential impacts on onshore surface water or groundwater would be limited to accidental spills of fuels, oils or chemicals associated with material handling, storage or refueling activities at the shore base. Such events are considered unlikely due to the implementation of secondary containment, designated storage areas, spill prevention measures and emergency response procedures.

In summary, with regard to their significance, the impacts on surface water and groundwater during the drilling operations phase are assessed as negative (-), of negligible intensity (IN=1), localised to the onshore port area (EX=1), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing port operations (SI=2), direct (EF=4), either periodic or occasional depending on the activity (PR=1-2), with short-term recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Impacts on surface water and groundwater                 |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.8.2.3 Demobilisation and abandonment phase

During demobilisation and abandonment, wastewater generation at the shore base will progressively decrease as personnel, equipment and temporary facilities are removed. Existing or temporary welfare facilities will remain available as required, with associated wastewater managed through existing port

services or authorised contractors until shore-base activities cease. No discharges to surface water or groundwater are anticipated, and no abstraction of freshwater resources will occur.

Waste from drilling operations, including non-hazardous and hazardous waste streams, will be temporarily staged at the shore base before being collected by licensed waste contractors and transported to authorised treatment, recovery or disposal facilities. Collection activities will involve vehicle movements, loading operations and the handling of sealed waste containers. Waste will be segregated, packaged and stored in appropriate containers in accordance with the Project Waste Management Plan, while hazardous wastes will be handled within designated containment areas and removed from the site as soon as practicable.

Measures for the safe management of waste will minimise the likelihood of spills reaching the port drainage system or infiltrating the ground. As waste collections are temporary, infrequent and undertaken within the existing port, with stormwater drainage infrastructure, any effects on the qualitative or quantitative characteristics of surface water or groundwater are expected to be localised, short term and of negligible significance.

Following completion of demobilisation, all temporary activities at the shore base will cease and no residual sources capable of affecting the qualitative or quantitative characteristics of surface water or groundwater will remain.

In summary, with regard to their significance, the impacts expected on surface water and groundwater during the demobilisation and abandonment phase are assessed as negative (–), of negligible intensity (IN=1), localised (EX=1), immediate (MO=4), coincident with demobilisation activities (PE=1), short-term reversible (RV=1), non-synergistic (SI=1), direct (EF=4), discontinuous (PR=1), of immediate recovery (MC=1), and non-cumulative (AC=1). In terms of their overall significance, these impacts are assessed as **negligible**.

## 10.1.9 Impacts on the anthropogenic environment

### 10.1.9.1 Spatial planning and land uses

This section assesses the potential impacts of the Project on spatial planning and land use, considering the baseline conditions presented in the ESBS Section 2.6.1 (Annex 02) and applying the impact assessment methodology described above. The assessment considers the extent to which Project activities may interact with existing spatial planning arrangements, designated land uses and the functional use of land during the preparation, drilling operations and demobilisation phases.

As established in the baseline, the offshore Project area (Block 2) contains no permanent settlements, terrestrial land uses or fixed infrastructure. Human activity within the concession area is exclusively maritime

in nature and comprises commercial shipping, fisheries and other sea uses, which are assessed separately in Section 10.1.9.1.2 (Maritime Uses). Consequently, the present assessment focuses primarily on the temporary interaction of the Project with the existing onshore logistical facilities required to support offshore drilling.

The onshore component of the Project is confined to existing operational facilities within the Port of Igoumenitsa and Corfu International Airport. The Port of Igoumenitsa will function as a temporary logistics base for the storage, handling and transfer of drilling equipment, materials and wastes, while Corfu International Airport will support helicopter transfers of personnel between shore and the Mobile Offshore Drilling Unit (MODU). Project activities will be undertaken entirely within existing operational areas that are already designated for port and airport functions. No permanent infrastructure, land acquisition, reclamation, dredging, rezoning or modification of existing planning designations will be required.

The relevant VR for this assessment is Spatial Planning and Land Use, which has been assigned **medium significance**. Although the Project does not involve permanent occupation or conversion of land, temporary use of operational areas within the Port of Igoumenitsa and the establishment of a temporary helicopter support facility at Corfu International Airport represent direct interactions with existing land uses. The receptor significance also reflects the strategic planning context within which the Project is located, including the Regional Spatial Frameworks for the Ionian Islands and Epirus, which recognise the importance of offshore hydrocarbon exploration and associated port infrastructure while requiring compliance with environmental safeguards. The receptor is therefore considered to be of moderate importance because Project activities interact with existing spatial planning arrangements, without however altering them.

### Regulatory compatibility

The compatibility assessment presented in Chapter 5 (Section 5.7) of this ESIA, examining the Project against the applicable spatial and urban planning frameworks in force in the study area, provides direct support for the assessment and is summarised below insofar as it is relevant to spatial planning, land use and settlement structure.

At national and regional strategic level, the Project is not in conflict with the goals of the General Framework for Spatial Planning and Sustainable Development (GFSPSD, GG 128/A/03-07-2008). Of particular relevance, the Regional Spatial Framework (RSF) of the Region of Epirus (MD ΥΠΕΝ/ΔΧΩΠΣ/78523/1208, GG 286/ΑΑΠ/28-11-2018) explicitly anticipates the Project type: among its identified priority functions for future port diversification at Igoumenitsa, the RSF Epirus lists *“support activities related to hydrocarbon exploration and production in the Northern Ionian and Epirus regions”* alongside cruise, bunkering and commercial freight functions. The Project's use of the port as a temporary logistics base for the Asopus-1 exploration well therefore represents an application of a function that the Region's own strategic spatial framework has proactively identified as a suitable future role for the port, rather than an unplanned or unanticipated land use.

At the level of onshore site-specific zoning, the Project's logistics base is located entirely within the Port Zone (designated Port Zone B4.5 under the approved GUP of the Municipality of Igoumenitsa, GG 575/AAP/31.12.2010). Determination of land uses within the Port Zone falls outside the scope of the GUP and is instead the statutory responsibility of the Port Planning and Development Committee (ESAL), under Article 19 of Law 2932/2001 (GG 145/A/2001) and Law 2971/2001 (GG 285/A/2001). The Port Master Plan, most recently revised by MD 8216/126/14, defines permitted land uses within the port zone as

“Services”, “Commercial Zone” and “Warehouses”, categories that expressly encompass logistics, storage, staging and support-service functions of the type required by the Project. The Project's onshore activities therefore fall within land uses already permitted under the current, approved zoning instrument, and do not require any amendment to the GUP, the Port Master Plan, or the ESAL-approved zoning.

The Special Spatial Planning and Sustainable Development Framework for Industry (JMD 11508/2009, GG 151/AAP/2009) similarly confirms that the Igoumenitsa area is designated for a complementary industrial/logistics role linked to the port's international gateway function, and that the Project's onshore facilities, being sited within the Port Zone, do not conflict with this Framework or with the National Spatial Planning Framework for Industry.

Collectively, these findings provide an important basis for the impact assessment presented below, supporting the conclusion that interactions with the Spatial Planning and Land Use receptor are limited to the temporary operational use of existing infrastructure and do not result in permanent changes to settlement structure, land use or the statutory planning framework.

#### 10.1.9.1.1 Drilling preparation and mobilisation phase

During the mobilisation phase, onshore activities affecting land use will be confined to the temporary establishment of the logistics base within the existing operational area of the Port of Igoumenitsa. These activities include the installation of temporary perimeter fencing, signage and directional markings, utility connections, prefabricated office units and welfare/sanitation facilities, and the mobilisation and (if applicable) installation of a wharf crane, together with onshore loading, unloading and staging of equipment and materials. At Corfu International Airport, mobilisation activities are limited to the installation and subsequent use of a temporary helicopter hangar within the existing operational airport area to facilitate crew transfers between the airport and the MODU.

Mobilisation activities are planned to take place within the boundaries of the existing, leased operational port area, within a Port Zone whose approved land use designation (Services / Commercial Zone / Warehouses, per the ESAL-approved Port Master Plan, MD 8216/126/14) already permits such activities. No change to the GUP of Igoumenitsa (GG 575/AAP/31.12.2010), to the ESAL zoning of the Port Zone, or to the port's concession or operational terms is required. The activities will be undertaken subject to the applicable port allocation, leasing and operational approvals. Similarly, the temporary helicopter hangar to be installed at Corfu International Airport will occupy existing airport land without altering the airport's land use designation, capacity, or management arrangements. The activities will be undertaken subject to applicable airport, aviation and operational approvals.

The installation of the wharf crane and onshore loading/unloading and staging activities represent a marginally greater, though still localised and temporary, interaction with land use, insofar as they may require the temporary allocation of specific operational areas within the port that would otherwise be available for routine port business and may involve minor demand on local contractors for crane mobilisation and civil works.

In summary, with regard to their significance, the impacts on spatial planning and land use during the mobilisation phase are assessed as negative (–), with negligible intensity (IN = 1), localised spatial extent confined to the project footprint (EX = 1), occurring immediately during mobilisation activities (MO = 4),

coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with no to low synergistic interaction with other port-based logistics activities (SI = 1–2), direct effect (EF = 4), discontinuous / occasional in nature (PR = 1), characterised by immediate recovery potential (MC = 1), and non-cumulative (AC = 1). Given the confirmed regulatory compatibility set out above, these impacts remain, in terms of their overall significance, **negligible**.

| Impacts on Spatial Planning and Land Use                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.9.1.2 Exploration drilling operations phase

During the drilling operations phase, onshore land-use interactions will be limited to the continued operation of the logistics base within the Port of Igoumenitsa, comprising the routine use of facilities, equipment and vehicles in support of offshore operations, and the associated, temporary occupation of designated port areas for storage, waste staging and vessel support. As set out in the ESBS Section 2.6.1.4 (Annex 02) and confirmed by the Chapter 5 compatibility assessment, the Project's use of the port will take place entirely within the existing leased operational area, within land uses already permitted, and will not require any change to established land use designations, port zoning arrangements or existing infrastructure.

The principal potential interaction with land use during this phase concerns the temporary allocation of port space to Project logistics functions, which may result in localised and intermittent disruption to the normal pattern of port activities (e.g. competing demand for quay space, storage areas or vehicle circulation routes). Given that the Port of Igoumenitsa is an established, multi-user commercial and passenger port with substantial existing operations, and that the Project's onshore footprint and workforce (approximately six shore-based personnel) are modest in scale, this interaction is expected to remain minor and readily managed through routine coordination with the Igoumenitsa Port Authority.

No new construction, land take, or capacity expansion is associated with these activities, and no interaction with land use beyond the existing port boundary is anticipated. Corfu International Airport will continue to be used for helicopter transfers and operation of the temporary hangar within the existing airport area, without affecting its land use, capacity or operational arrangements.

In summary, with regard to their significance, the impacts on spatial planning and land use during the drilling operations phase are assessed as negative (-), of negligible intensity (IN = 1), localised to the operational footprint of the port (EX = 1), immediate (MO = 4), temporary throughout the drilling period (PE = 1), short-term and fully reversible following cessation of activities (RV = 1), with moderate synergistic interaction with existing port operations (SI = 2), direct (EF = 4), continuous throughout the drilling campaign (PR = 4), with short-term recovery potential (MC = 1), and non-cumulative (AC = 1). Overall, these impacts are assessed as **minor**.

| Impacts on Spatial Planning and Land Use                 |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |     |                            |                     |

| Logistics base operation - disruption to port activities | -          | 1              | 1           | 4           | 1                | 1                  | 2           | 4           | 4                | 1             | 1                 | 23                    | Low | Medium                     | MINOR               |

### 10.1.9.1.3 Demobilisation and abandonment phase

Demobilisation activities will involve the dismantling and removal of the temporary logistics base from the Port of Igoumenitsa, including containers, prefabricated units, fencing, signage and utility connections, together with the removal of the temporary helicopter hangar from Corfu International Airport, except for any assets agreed with the relevant facility operator to be retained or otherwise transferred. These activities allow the relevant areas to be handed back in the condition agreed with the relevant facility operator.

Since no permanent structures will have been constructed and no change to land use designation, the demobilisation phase is expected to fully reinstate baseline land-use conditions at both the port and the airport, with the cessation of Project-related occupation of operational space and the associated release of that space for routine port and airport activities. This represents a minor beneficial interaction with the land use / spatial planning receptor, associated with the removal of temporary occupation and the restoration of full operational availability to the port and airport.

In summary, with regard to their significance, the impacts on settlement structure and land use during the demobilisation and abandonment phase are assessed as positive (+), of minor intensity (IN = 2), localised spatial extent (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the demobilisation period (PE = 1), short-term and fully reversible (RV = 1), non- to lowly synergistic (SI = 1), direct effect (EF = 4), continuous throughout the demobilisation period (PR = 4), with short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **positive**.

| Impacts on Spatial Planning and Land Use   |            |   |                |   |             |   |             |   |                  |   |                    |    |              |        |             |  |                  |  |               |  |                   |  |                       |  |                            |  |                     |  |

### 10.1.9.2 Maritime uses

This section assesses the potential impacts of the Project on maritime uses, drawing among others on the baseline characterisation presented in ESBS Sections 2.6.2 and 3.3.1.5 (Annex 02), together with additional information received through consultation with the competent authorities. Maritime uses comprise the principal human activities undertaken within the wider Project area and include shipping and navigation, commercial fisheries, aquaculture, maritime tourism, submarine telecommunications infrastructure, military training and exercise activities, and other offshore installations (oil and gas, and offshore renewables).

In addition to the information included in the ESBS, consultation with the Hellenic Coast Guard (Central Port Authority of Corfu, the Central Port Authority of Igoumenitsa) and the Hellenic Navy Hydrographic Service has provided further information on maritime activities and constraints within and around Block 2. The Central Port Authority of Corfu (Ref. 2131.1/4152/2026, dated 16 July 2026) confirmed that Block 2 is an open navigation area that may be transited by vessels engaged in international and domestic voyages, including cargo vessels, tankers, general cargo vessels and other professional or private craft, although no designated shipping routes or statistical data on vessel passage frequency are available. No scheduled passenger, passenger/vehicle or cargo services were reported to transit the area. Increased activity by recreational craft, sailing vessels, professional tourist vessels, large private yachts and, depending on voyage plans and operational requirements, cruise vessels may occur particularly during the summer period. The same authority confirmed that there are no designated anchorage areas or permanent or seasonal fishing zones in the wider marine area, although professional and coastal fishing activities occur in the wider area. No areas of high fishing or tourist vessel visitation were identified within the area of interest. The area may also be used, as required, for search and rescue (SAR), surveillance and policing, and marine pollution response operations, while scientific, oceanographic, hydrographic and geophysical surveys may take place subject to the relevant approvals and permits.

The Central Port Authority of Igoumenitsa (Ref. 2121.4/2502/26, dated 7 July 2026) additionally confirmed that ocean-going vessels engaged in international maritime transport may transit the wider area, although the Authority does not hold information on such traffic as the area falls outside its jurisdiction. It further noted that scheduled passenger/vehicle ferry routes serving the Port of Igoumenitsa and connecting with Italian ports operate through the Corfu Straits and along the coast of Thesprotia and therefore do not pass through or lie adjacent to Block 2.

In relation to military activities and submarine telecommunications infrastructure, the Hellenic Navy Hydrographic Service, in correspondence dated 3 July 2026 in response to a request for geospatial data concerning maritime activities within Block 2, confirmed that there are no shipwrecks, permanently established military exercise areas, or areas currently temporarily reserved through NAVTEX and/or Notices to Mariners within Block 2.

This information, together with a dedicated Shipping and Navigation Assessment commissioned to quantify vessel traffic interactions with the proposed exclusion zone (Annex 08), has been used to refine the assessment of maritime use interactions presented below.

Unlike the spatial planning and land use receptor, which is limited to the temporary use of existing onshore infrastructure, the maritime uses receptor directly overlaps with the offshore Project area. Project activities, particularly the temporary establishment of the statutory 500 m safety exclusion zone, support vessel movements between the Port of Igoumenitsa and the well location, and temporary operational restrictions during drilling, have the potential to interact with existing maritime activities within Block 2 and the surrounding waters.

The maritime uses valued receptor has therefore been assigned **high significance**, reflecting the strategic importance of shipping and navigation within the northern Ionian Sea, the presence of commercial fishing grounds in the wider Project area, and the temporary restriction of access associated with offshore drilling operations. Other maritime uses, including aquaculture, maritime tourism, submarine telecommunications cables, military activities and offshore energy installations, have also been considered in the assessment; however, based on the baseline review and information obtained from the competent authorities, these receptors are either spatially separated from the Project or do not occur within the immediate vicinity of Block 2. Consequently, they contribute to the overall receptor significance but are expected to experience limited or no direct interaction with Project activities.

### Maritime Spatial Planning Framework

The Project is located within the offshore exploration concession designated as Block 2 in the northern Ionian Sea, an authorised maritime use under Law 4525/2018 and the national maritime spatial planning framework established under L.4546/2018, as amended, and the National Spatial Strategy for Maritime Space (NSPSMS), approved by Cabinet Act 6/17-04-2025. Block 2 falls within Spatial Unit 4 of the NSPSMS. No designated Maritime Spatial Planning measure or statutory marine zoning provision has been identified that would preclude hydrocarbon exploration within Block 2, and the Project remains compatible with other lawful maritime activities through the implementation of standard maritime notification procedures (NAVTEX, Notices to Mariners) and navigational safety measures during drilling.

### Shipping and Navigation

Shipping and navigation represent the maritime use with the greatest potential spatial interaction with the Project. ESBS Section 2.6.2.2 (Annex 02) identifies well-defined NW–SE commercial shipping corridors linking the Adriatic with western Greece, together with cargo, tanker and passenger ferry routes connecting Italian Adriatic ports with Igoumenitsa and Patras. The proposed Asopus-1 well lies close to, but outside, the highest-density shipping routes mapped by EMODnet in the wider area.

Correspondence from the Central Port Authority of Igoumenitsa (Ref. 2121.4/2502/26, dated 7 July 2026) and the dedicated Shipping and Navigation Assessment prepared for the Project (Annex 07), provides additional site-specific information and a more detailed characterisation of vessel traffic in proximity to Asopus-1. This information refines and supplements, but does not materially alter, the baseline understanding of shipping and navigation presented in the ESBS. In particular, the Shipping and Navigation Assessment confirms the presence of passing commercial, tanker and passenger vessel traffic in the wider area, while indicating that the highest-density traffic is concentrated primarily to the northeast and east of Asopus-1 and that the well location is outside the principal high-density shipping routes. The assessment also identified no regularly scheduled Ro-Pax route within the study area, consistent with the Central Port Authority of Igoumenitsa's confirmation that the principal Igoumenitsa–Italy Ro-Pax route operates through the Corfu Channel and does not intersect or adjoin Block 2.

The findings of the Shipping and Navigation Assessment, including the characterisation of vessel traffic and assessment of potential navigational hazards, are used to inform the assessment of effects associated with the temporary 500 m safety exclusion zone around the MODU in the following sections.

### Commercial Fisheries

As set out in ESBS Section 2.6.2.3 (Annex 02), the Asopus-1 well is located within GSA 19 (Western Ionian Sea), while Block 2 as a whole spans GSA 19 and GSA 20. Commercial fishing activity in the wider study area is undertaken by both Greek and Italian small-scale coastal fleets, together with a lower level of offshore fishing effort. Global Fishing Watch data indicate that, although fishing intensity at the Asopus-1 location is lower than in coastal waters, the area forms part of a wider seascape regularly traversed by commercial fishing vessels. In addition, the GFCM deep-water Fisheries Restricted Area, which bans towed dredges and trawl nets in waters deeper than 1,000 m, already excludes bottom-contact fishing gear from those portions of Block 2 exceeding this depth, independently of the Project's exclusion zone. Fisheries are therefore identified as the maritime use most likely to interact directly with Project operations, principally through the temporary safety exclusion zone and the movement of support/supply vessels and are assessed accordingly in the phase-specific tables below.

### Aquaculture

ESBS Section 2.6.2.4 (Annex 02) confirms that aquaculture activity in the wider study area is confined to designated Aquaculture Development Areas (ADAs) along the north-eastern coast of Corfu (Code E.5) and within the POAY of Thesprotia, both located within sheltered coastal waters. No ADA, Organised Aquaculture Development Area (OADA) or individual aquaculture unit has been identified within Block 2 or in the vicinity of the Asopus-1 well. Given this spatial separation, no interaction between Project activities and aquaculture operations is anticipated during any Project phase, and aquaculture is scoped out of the phase-specific assessment tables presented below.

### Maritime Tourism and Recreational Navigation

ESBS Section 2.6.2.5 (Annex 02) identifies the principal recreational navigation corridors (the Corfu Channel, the Corfu–Paxos–Antipaxos route, and coastal cruising routes along the Epirus mainland) as being concentrated in the eastern and south-eastern portions of the wider Project area, well inshore of the Block 2 boundary. The open-sea location of the Asopus-1 well does not constitute a principal recreational navigation or cruise corridor, although it may occasionally be crossed by vessels undertaking longer offshore passages between Greece and Italy. Given the limited and infrequent nature of this potential interaction, maritime tourism is not carried forward as a discrete line item in the phase-specific impact tables, but any residual interaction with occasional offshore-passage traffic is captured within the general vessel-traffic assessment addressed under Shipping and Navigation above.

### Submarine Telecommunications Cables

ESBS Section 2.6.2.6 (Annex 02) identifies three international submarine cable systems (Eagle, Jonah and AAE-1) within the wider study area, based on publicly available information and open-source cable databases. Consultation with Cosmote has provided additional operator-specific GIS data for two of its submarine cable routes between Bari and Kokkini, located approximately 24 km and 29 km from the proposed Asopus-1 well. In addition, the LOT 01 geophysical survey campaign identified four cable segments within the surveyed area (ESBS Section 3.3.1.5, Table 38 – Annex 02). Three groups of detected cable

segments (EER001\_CBL-02, -03 and -04) were interpreted by the survey team as corresponding to the AAE-1 system, based on their characteristics and consistency with the route shown in the Submarine Cable Map database. The fourth detected cable (EER001\_CBL-01), located in the north-eastern part of the surveyed area, has not been conclusively attributed to a specific owner or cable system. As confirmed through correspondence with the Hellenic Navy Hydrographic Service, submarine cable records held in its Chart Database are classified by the respective cable owners, and any future requests for geospatial data from the Hydrographic Service require prior authorisation from the Ministry of National Defence.

The operator-provided GIS data and Project-specific geophysical survey findings provide the most direct evidence available for characterising submarine cable infrastructure in the vicinity of the Project, while the open-source datasets provide wider regional context. The interpretation of the survey-detected cable segments as corresponding to named cable systems has not been independently confirmed by the respective cable owners and is therefore treated with appropriate caution in the assessment. As a precautionary measure, and consistent with International Cable Protection Committee (ICPC) guidance, the Project will notify Cosmote and the relevant charting authorities of the planned drilling and vessel-transit operations prior to mobilisation, notwithstanding the confirmed separation distances between the Project footprint and the identified cable routes. On this basis and given that no cable route has been identified within the drilling footprint or 500 m safety exclusion zone, no direct physical interaction between Project activities and submarine cables is anticipated during any phase of the Project. The residual risk will be further addressed through official notification and avoidance procedures.

### **Military Training and Exercise Areas**

In response to the Project's request for information on military exercise areas, the Hellenic Navy Hydrographic Service confirmed that there are no permanently established exercise areas, and no temporary restricted or reserved areas currently in force through NAVTEX broadcasts and/or Notices to Mariners, within the boundaries of Block 2 and the location of the Asopus-1 well. In line with the ESBS baseline findings of Section 2.6.2.7 (Annex 02), no interaction between Project activities and military training or exercise areas is identified for any Project phase; this receptor is therefore scoped out of the phase-specific tables below.

### **Other Offshore Installations**

As set out in ESBS Section 2.6.2.8 (Annex 02), no offshore oil and gas installation or operational offshore renewable-energy installation has been identified within the immediate area of the Asopus-1 well or within a 100 km buffer around it. The nearest oil and gas installation (AQUILA 2, closed down) and the nearest planned offshore wind farm areas ("Santa Maria di Leuca" and "Puglia 1", approximately 10–15 km distant, in Italian waters) are sufficiently separated, both spatially and temporally (in the case of planned wind farms, which are not yet under construction), that no direct interaction with Project activities is anticipated in any phase. This receptor is accordingly scoped out of the phase-specific tables below.

The interactions identified for shipping, fisheries and general vessel-related activities are carried forward into the three phase-specific assessments below, applying the Methodology as described in Section 10.1.1.3.1 and the Maritime Uses VR significance of High.

#### 10.1.9.2.1 Drilling Preparation and Mobilisation Phase

During the mobilisation phase, interactions with maritime uses arise principally from the temporary occupation of port waters and quay space by the wharf crane (if applicable), onshore loading, unloading and staging of drilling equipment and materials, and the transit of the MODU and its support vessels from their point of mobilisation to the Asopus-1 well site. These activities are transitory and spatially confined to the Port of Igoumenitsa's operational waters and the MODU's transit route, and do not involve the establishment of the drilling safety exclusion zone, which is only implemented once the MODU is on station.

The Shipping and Navigation Assessment prepared for the Project (Annex 07) provides the relevant site-specific baseline context for vessel traffic in the vicinity of Asopus-1. The assessment is based on seven months of AIS data collected between 1 May and 30 November 2025, supplemented by a further five months of AIS data covering 1 December 2025 to 30 April 2026. Over the full 12-month period, an average of 18 unique vessels per day was recorded within the 10 nm study area, with traffic patterns broadly consistent with those observed during the initial seven-month assessment. Higher-density traffic was concentrated primarily in the northeastern part of the study area, including a NW–SE route east of Asopus-1 associated largely with regularly scheduled Roll-on/Roll-off (RoRo) cargo vessels, while lower-density areas were identified to the west and south. The Asopus-1 location itself was characterised as an area of medium vessel density relative to the wider study area. Within 1 nm of Asopus-1, an average of one unique vessel every one to two days was recorded over the full 12-month period.

It is noted that hazards associated with the transit of Project vessels within port limits and along the passage between Igoumenitsa and Asopus-1 are not examined within the Shipping and Navigation Assessment, as these are expected to be managed by the relevant ports and through compliance with standard navigational safety management and applicable port and maritime procedures. The assessment instead focuses on hazards arising while the MODU is located at the Asopus-1 site, which are addressed in Section 10.1.9.2.2 below. Accordingly, the mobilisation-phase assessment draws on the Shipping and Navigation Assessment primarily to characterise the surrounding vessel traffic environment and to provide context for the potential interaction of Project vessel movements with other maritime users during mobilisation.

The presence of higher-density commercial traffic elsewhere within the wider study area, including the RoRo route identified to the east and northeast of Asopus-1, is recognised as part of the navigation context for mobilisation. However, the Asopus-1 location is not itself situated within this highest-density traffic routeing, and the temporary transit of the MODU and support vessels will be managed through standard navigational safety measures, as described below.

This is consistent with confirmation received from the Central Port Authority of Corfu (Ref. 2131.1/4152/2026, dated 16 July 2026) and the Central Port Authority of Igoumenitsa (Ref. 2121.4/2502/26, dated 7 July 2026), which confirms that Block 2 is an open navigation area that may be transited by vessels engaged in international and domestic voyages, but that no designated shipping routes or scheduled passenger, passenger/vehicle or cargo services pass through Block 2. The Central Port Authority of Igoumenitsa further confirmed that the principal Igoumenitsa–Italy Ro-Pax route operates through the Corfu Strait and along the coast of Thesprotia rather than through or adjacent to Block 2. The Hellenic Navy Hydrographic Service further confirmed, in correspondence dated 3 July 2026, that there are no permanently established military exercise areas, temporarily reserved areas or shipwrecks within Block 2; these features are therefore not considered to have the potential to interact with mobilisation activities.

The temporary movement of the MODU and support vessels will be managed through appropriate passage planning, navigational watches, AIS operation, VHF communications and compliance with applicable Collision Regulations (COLREGs), Safety of Life at Sea (SOLAS) requirements and port requirements. These measures will enable the Project vessels to identify and respond appropriately to other vessels encountered during mobilisation and to maintain safe separation in accordance with applicable navigation requirements.

Within the Port of Igoumenitsa, mobilisation activities are planned to take place within the boundaries of the existing leased operational port area and within a Port Zone whose approved land-use designation permits the relevant activities. The installation and mobilisation of the wharf crane, where applicable, together with onshore loading, unloading and staging activities, may require the temporary allocation of specific quay and adjacent water areas that would otherwise be available for routine port operations and vessel movements. These interactions are therefore expected to result in a marginal, localised and temporary disruption to normal port use, but will take place within an existing operational port environment and will be managed through coordination with the Port Authority and applicable port procedures.

In summary, with regard to their significance, the impacts on maritime uses during the mobilisation phase are assessed as negative (-), of negligible to low intensity (IN = 1-2), localised to the port operational footprint or the MODU transit corridor (EX = 1), occurring immediately upon commencement of the relevant activity (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction with concurrent port and vessel traffic (SI = 2), direct in effect (EF = 4), discontinuous in occurrence (PR = 1), with immediate to short-term recovery potential (MC = 1), and non-cumulative (AC = 1). Given the High significance of the Maritime Uses receptor, impacts of negligible magnitude are elevated to Minor in the final significance rating; overall, impacts during this phase are assessed as **Minor**.

#### 10.1.9.2.2 Exploration drilling operations phase

During the drilling operations phase, the principal interaction with maritime uses is the temporary establishment of the 500 m safety exclusion zone around the MODU for the duration of drilling (up to 90 days, conservatively assessed), together with routine support and supply vessel movements between the Port of Igoumenitsa and the well site. These activities may require temporary separation from or minor adjustment by other marine users operating in the immediate vicinity of the Project.

Other Project activities, including drillship dynamic positioning, drilling, wellhead and casing installation, WBM fluid and cuttings discharge, MODU and support/supply vessel power generation, vertical seismic profile (VSP) survey activities, MODU lighting and ROV operations, are expected to have only limited and highly localised interaction with maritime uses. These activities do not require additional exclusion areas or permanent changes to established navigation routes and, where relevant, are managed within the overall operational and maritime safety arrangements for the drilling campaign. The existing Igoumenitsa logistics base will continue to operate within the established port environment, with any interaction with other port users managed through normal port coordination procedures.

This phase corresponds to the period assessed in detail by the Shipping and Navigation Assessment (Annex 07), which applied the IMO Formal Safety Assessment (FSA) process (IMO, 2018) to the baseline vessel traffic characterised over a 12-month AIS dataset (18 unique vessels per day on average; cargo vessels 62%, tankers 20%, passenger vessels 11%, recreational vessels ( $\leq 24$  m) 6%; average vessel length 171 m, draught 7.4 m, average speed 12.7 kt). Within 1 nm of Asopus-1, an average of one vessel every one to two days was recorded over the 12-month period, falling to approximately one vessel every two to three days within 0.5 nm. The recorded traffic was predominantly tankers and containerships, including a band of routeing LPG tankers on a north-south bearing. While individual vessels have passed close to the well location, the baseline does not indicate a continuously occupied or high-density shipping route immediately surrounding Asopus-1.

Of particular relevance to the assessment of disruption to established maritime services, none of the regularly scheduled RoRo vessels operating in the wider study area, including services by DFDS Seaways, Ulusoy, Grimaldi Line and Polish Ocean Lines between Italian and Turkish ports, were recorded passing within 500 m of the well location during the 12-month baseline period, and only two occasions were recorded within 1 nm. No regularly scheduled Ro-Pax service was identified within the study area. The Central Port Authority of Igoumenitsa has also confirmed that the Igoumenitsa–Italy Ro-Pax route is routed through the Corfu Straits, clear of Block 2. The temporary Project safety zone is therefore not expected to materially interfere with established scheduled passenger or freight services.

Three shipping and navigation hazards were identified and assessed under the FSA methodology: (i) collision of a third-party vessel with a Project vessel; (ii) works causing disruption to passing vessel routeing/timetables; and (iii) vessel displacement leading to an increased risk of collision between third-party vessels. The assessment concluded that, with the embedded maritime safety measures in place, all three hazards are within the acceptable or tolerable-if-ALARP region. These measures include the MODU's status as restricted in ability to manoeuvre (RAM), associated collision risk management procedures, 24/7 watchkeeping, AIS and ARPA monitoring, appropriate lights and shapes, the temporary 500 m safety zone, promulgation of NAVTEX messages and Notices to Mariners by the Hellenic Coast Guard, an Emergency Response Plan (including a contingent Emergency Disconnect Sequence), and liaison with the fishing industry. Advance notice of operations to the main operators of regularly scheduled vessels will provide an additional precautionary measure.

The FSA findings therefore indicate that, although the temporary exclusion zone and vessel movements represent the principal maritime-use interaction, these are not expected to result in material disruption to established commercial navigation or an appreciable change in overall navigational risk, provided the identified controls are implemented.

Fishing vessel interactions were also considered: fishing vessels comprised approximately 1% of vessel tracks recorded in the study area (approximately one transit every four days over the 7-month period), with AIS data likely under-representing vessels of less than 15 m in length, which are not required to broadcast. GFCM data (as of April 2026) records 343 vessels authorised for demersal trawling in the Ionian Sea (222 Greek, 106 Italian and 15 Maltese flagged), the majority (85%) exceeding 15 m in length, some of which may operate in the vicinity of Asopus-1. This is consistent with the ESBS baseline confirmation that the GFCM Deepwater Fisheries Restricted Area, which bans towed dredges and trawl nets in waters deeper than 1,000 m, already excludes bottom-contact fishing gear from those portions of Block 2 exceeding this depth, independently of the Project's safety exclusion zone, and with correspondence from the Central Port Authority of Corfu confirming there are no designated anchorage areas or permanent/seasonal fishing zones in the wider area, although professional and coastal fishing activity occurs more generally in the region.

Navigational features of relevance to this phase include subsea cables (the closest charted cable passing approximately 1.1 nm to the west, broadly consistent with the Project-specific geophysical survey finding that the nearest identified AAE-1 cable segment passes a minimum of 2,692 m from the well), an ODAS meteorological/oceanographic buoy 7.5 nm to the northwest, and a charted explosives ground 6.6 nm to the north; there are no ports or harbours in the immediate vicinity, the nearest (Ammos Port and Mathraki Port, Othonoi/Diapontian Islands, and Porto Turistico di Santa Maria di Leuca, Italy) lying 23-29 nm distant and serving predominantly recreational and small ferry traffic. No permanently established or NAVTEX-activated military exercise areas, and no known shipwrecks, are present within Block 2 (Hellenic Navy Hydrographic Service, 3 July 2026).

In summary, with regard to their significance, the impacts on maritime uses during the drilling operations phase are assessed as negative, but predominantly of negligible to low intensity (IN = 1–2), with effects largely confined to the immediate Project footprint and the temporary safety exclusion zone and vessel transit corridor (EX = 1–2). Effects are immediate in onset (MO = 4), temporary and limited to the drilling campaign (PE = 1), short-term and fully reversible following cessation of the relevant activity (RV = 1), and generally non-synergistic or only weakly synergistic with concurrent maritime traffic (SI = 1). The majority of activities have a limited or indirect relationship with maritime users (EF = 1–2), with continuous interaction restricted principally to the temporary safety zone and routine vessel transfers and more occasional interaction associated with discrete activities such as VSP surveys (PR = 1–2). Recovery is expected to occur promptly following cessation of the relevant activity (MC = 1), and the effects are non-cumulative (AC = 1).

Given the High significance of the Maritime Uses receptor, the resulting impacts are predominantly **Minor**, with **Moderate** significance retained only for the principal direct interaction associated with the temporary MODU safety exclusion zone and support/supply vessel movements. The remaining activities, including drillship dynamic positioning, drilling and wellhead/casing installation, WBM discharges, MODU and support/supply vessel power generation, VSP activities, MODU lighting, ROV operations and logistics-base operation, are expected to result in Minor impacts on maritime uses because their interaction with maritime users is limited, localised, temporary and reversible, and they do not require additional restrictions on established navigation routes. For impacts categorized as Moderate, mitigation/prevention/remediation measures are proposed within the current report in order to reduce them to at least Minor. Following the implementation of the relevant measures, as proposed in Chapter 11 of the present report, the residual impacts are assessed as **Minor**.

| Impacts on Maritime Uses                                                            |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |                                  |

### 10.1.9.2.3 Demobilisation and Abandonment Phase

Demobilisation activities involve the sealing and abandonment of the well (cement plug installation, MODU circulation and surface handling operations), the removal of any temporary subsea infrastructure, and the dismantling and removal, or agreed asset retention or transfer, of the temporary logistics base from the Port of Igoumenitsa. With the exception of the residual, negligible interactions associated with well-sealing operations, these activities are associated with the removal of the safety exclusion zone and the restoration of unrestricted access to the water column previously occupied by the MODU, as well as the release of port operational space back to routine port business.

As with the mobilisation phase, the Shipping and Navigation Assessment (Annex 07) does not extend its quantitative hazard analysis to the transit of the MODU and support vessels away from Asopus-1 back to port, this being managed through standard passage planning, COLREGs/SOLAS compliance and port control; the baseline traffic characterisation summarised in Section 10.1.9.2.2 nonetheless indicates ample sea room either side of the vessel's departure route, with the highest-density shipping corridor remaining well to the east of the well location. Removal of the safety exclusion zone will reinstate unrestricted navigation and

fishing access. Similarly, the release of quay space and port waters upon dismantling of the logistics base will allow the relevant areas to be handed back in the condition agreed with the Port operator.

In summary, with regard to their significance, the impacts on maritime uses during the demobilisation and abandonment phase associated with well-sealing operations are assessed as negative (–) but of negligible intensity (IN = 1), localised extent (EX = 1), immediate (MO = 4), temporary (PE = 1), short-term and fully reversible (RV = 1), non-synergistic (SI = 1), direct (EF = 4), discontinuous (PR = 1), with immediate recovery potential (MC = 1) and non-cumulative (AC = 1); overall, these residual impacts are assessed as **Minor**. By contrast, the removal of temporary subsea infrastructure and the dismantling and removal, subject to any agreed retention or transfer of assets, of the logistics base from the port area are assessed as positive (+), restoring baseline access and use of the marine environment and the operational availability of the port; these beneficial impacts are recorded as **Positive** in the final significance rating.

| Impacts on Maritime Uses                         |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.9.3 Structure and Functions of the Anthropogenic Environment

The assessment of potential impacts on the structure and functions of the anthropogenic environment considers the potential for Project activities to affect the structure and principal characteristics of the anthropogenic environment, including the urban fabric and settlement structure adjacent to the Project. In particular, it considers whether Project activities could result in fragmentation of urban or peri-urban areas or contribute to direct or indirect trends of upgrading or degradation of the existing settlement structure and urban environment.

As established in the ESBS (Annex 02), the offshore Project area within Block 2 contains no permanent settlements, urban fabric or terrestrial land uses. The onshore components of the Project are confined to existing, operational facilities at the Port of Igoumenitsa and Corfu International Airport. The Project does not require land acquisition, permanent land take, resettlement, new permanent buildings, or expansion of existing infrastructure. The temporary logistics base at the Port of Igoumenitsa will operate within the existing port zone, while the temporary helicopter hangar at Corfu International Airport will be installed within the existing airport area. Accordingly, the Project does not alter the established settlement pattern or the functional structure of the surrounding urban areas.

During the drilling preparation and mobilisation phase, temporary activities at the Port of Igoumenitsa, including the installation of temporary fencing, signage, prefabricated office and welfare facilities, equipment

staging and logistics operations, will be undertaken within the existing operational port area. These activities may temporarily modify internal circulation and the use of operational space within the port but will not extend into adjacent settlements or result in fragmentation of the wider urban fabric. Similarly, the temporary helicopter hangar and associated helicopter operations at Corfu International Airport will remain within the existing airport operational area and will not alter the surrounding settlement structure or land use pattern.

During the exploration drilling operations phase, activities will be predominantly offshore. The drillship will operate within Block 2, while support vessel movements will take place within the established maritime environment. The temporary 500 m safety exclusion zone around the drillship may temporarily restrict access to a limited area of marine space for other users, but this does not affect the physical structure or functional organisation of adjacent settlements or urban areas. Onshore logistics activities at the Port of Igoumenitsa will continue to use existing operational areas and will not require permanent changes to the port or surrounding urban environment.

During demobilisation and abandonment, temporary facilities and equipment associated with the logistics base and helicopter support arrangements will be removed, retained or transferred as agreed with the relevant facility operator, and the operational areas will be handed back in the agreed condition.

Overall, the Project is not expected to result in fragmentation of the urban structure, alteration of settlement patterns, or degradation of the principal characteristics and functions of the anthropogenic environment. Any temporary changes in the internal use or circulation of existing port and airport operational areas are limited in extent and duration and do not affect the adjacent urban fabric or settlements. Conversely, the removal of temporary facilities following completion of the exploration programme will restore the existing functional arrangements.

The Structure and Functions of the Anthropogenic Environment Valued Receptor is therefore considered to be of **Low significance**. Given the absence of permanent construction, land take, resettlement, expansion of the existing infrastructure footprint, or interaction with the urban fabric and settlement structure the receptor is **scoped out** of further detailed impact assessment.

#### 10.1.9.4 Cultural Heritage

This section assesses the potential impacts of the Project on cultural heritage, drawing on the baseline conditions presented in ESBS (Annex 02), the Archaeological Baseline Assessment Report prepared by the GeoSat ReSeArch Lab of the Foundation for Research and Technology Hellas – Institute for Mediterranean Studies (FORTH-IMS) (Annex 06), and correspondence received from the Ephorate of Underwater Antiquities (EUA) in response to the Project's request for information on underwater cultural heritage within the Block 2 marine area (Ref. 138577, dated 27 April 2026).

Cultural heritage within the study area comprises two components: (i) terrestrial cultural heritage, encompassing the designated archaeological sites, historic settlements, fortifications and listed monuments of the Corfu and Thesprotia Regional Units (ESBS Section 2.6.3.1); and (ii) underwater cultural heritage, reflecting the recognised archaeological significance of the northern Ionian Sea as a maritime cultural landscape and, in particular, the identification of a target interpreted as a probable ancient shipwreck (Target T057) identified within the LOT 01 survey area (ESBS Sections 2.6.3.2 and 3.3.1.12).

The Cultural Heritage Valued Receptor has been assigned **High significance**. This reflects the recognised maritime archaeological importance of the Corfu–Otranto corridor within which Block 2 is situated and, most directly, the identification of Target T057 as the probable remains of an ancient merchant vessel with an associated amphora cargo. Although terrestrial heritage assets lie entirely outside the Project’s onshore and offshore footprint, the potential presence of an underwater cultural heritage asset within the wider survey area makes Cultural Heritage a highly sensitive receptor for which avoidance and protection measures are warranted.

### Terrestrial cultural heritage

As established in the ESBS, the Corfu Regional Unit and the Municipality of Igoumenitsa contain numerous designated cultural heritage assets, including the UNESCO World Heritage-inscribed Old Town of Corfu, the Fortress of Igoumenitsa, and a range of other listed monuments and archaeological sites. None of these designated assets is located within, or in the immediate vicinity of the Project’s onshore operational footprint. The onshore components of the Project are confined to existing, already-developed operational areas within the Port of Igoumenitsa (Port Zone B4.5) and Corfu International Airport, and involve no land acquisition, excavation or ground-disturbing works beyond any limited works required within existing operational surfaces. No direct or indirect interaction between Project activities and any designated terrestrial cultural heritage asset is anticipated during any Project phase.

Notwithstanding the absence of any known asset within the Project footprint, any ancillary ground-disturbing works undertaken onshore, if required, will be carried out in accordance with the requirements of Law 4858/2021, including prior consultation, where relevant, with the competent Ephorate of Antiquities of Corfu or the Ephorate of Antiquities of Thesprotia, and implementation of a Chance Finds Procedure in the event that previously unrecorded archaeological material is encountered. On this basis, terrestrial cultural heritage is not assessed further in the tables below.

### Underwater cultural heritage

The LOT 01 geophysical and visual inspection survey identified Target T057 at a water depth of 880.04 m (ESBS Table 3.12, Section 3.3.1.12- Annex 02), interpreted by FORTH-IMS as the remains of an ancient merchant vessel associated with a cargo of transport amphorae, with both exposed and buried archaeological deposits preserved on the seabed. The target comprises an isolated, elongated seabed anomaly measuring approximately 23.7 m by 8.3 m and rising approximately 0.6 m above the surrounding seabed, with sub-bottom profiler data indicating buried material extending a further 2.20 m below the seabed. Visual inspection using the CathX camera system confirmed a concentration of partially buried amphorae, of a form broadly consistent with Adriatic production-sphere types (Lamboglia 2 and Dressel 6A). Although the available evidence does not permit secure typological or chronological attribution, the observable characteristics are consistent with an ancient shipwreck of high archaeological significance.

The Archaeological Baseline Assessment Report identifies the potential mechanisms by which underwater cultural heritage could be affected by offshore project activities. Direct impacts could arise from seabed penetration associated with drilling or from the placement of temporary infrastructure on the seabed, potentially resulting in physical damage, displacement or destruction of archaeological deposits, should such remains occur within the affected area. Indirect impacts could arise from localised sediment disturbance, accidental contact with previously unidentified material, or unplanned activities outside the intended operational footprint.

In relation to the proposed Project, Target T057 is located approximately 8,606 m (8.6 km) north of the proposed Asopus-1 well location and therefore lies well outside the 500 m safety exclusion zone to be established around the MODU during drilling operations. Target T057 is also not expected to be affected by localised seabed deposition associated with WBM fluids/cuttings or cement discharge, which are typically confined to the immediate vicinity of the wellhead. No other archaeological sites, anomalies or geophysical signatures indicative of underwater cultural heritage were identified within the project footprint or within the 500 m assessment area surrounding the proposed drilling location. This finding is consistent with the response received from the EUA (Ref. 138577, dated 27 April 2026), which confirms that no information is currently available to the authority indicating the presence of underwater antiquities or declared underwater archaeological sites within the relevant marine area. The EUA nevertheless notes that ancient and modern shipwrecks have been identified during previous investigations in the wider marine area.

Accordingly, no direct physical interaction between planned Project activities and Target T057, or with any other known underwater cultural heritage asset, is anticipated during any Project phase. Nevertheless, the Archaeological Baseline Assessment Report notes that, while no archaeological targets were identified in the vicinity of the well location, the presence of deeply buried, currently unidentified archaeological material cannot be entirely excluded. This residual uncertainty is further recognised in the EUA correspondence, which has requested review of the detailed seabed survey results and, if considered necessary, an in-situ underwater archaeological inspection. Given this uncertainty, the **High significance** of the receptor, the archaeological potential of the wider Block 2 area, and the recognition that offshore areas of the northern Ionian Sea remain incompletely investigated archaeologically, potential underwater cultural heritage within the Project area will be addressed through appropriate avoidance and management measures, while Target T057 will remain outside the Project operational footprint. The specific measures proposed to avoid and manage potential effects on cultural heritage are set out in Chapter 11 (Mitigation Measures) of this ESIA.

#### 10.1.9.4.1 Drilling Preparation and Mobilisation Phase

Mobilisation-phase activities are confined to the existing operational areas of the Port of Igoumenitsa and Corfu International Airport, and to the transit of the MODU and support vessels to the Asopus-1 well site. None of these activities involves seabed disturbance, discharge, or any other interaction with the marine environment in the vicinity of Target T057 or any other known or suspected underwater cultural heritage feature, and no designated terrestrial cultural heritage asset is present within or adjacent to the onshore logistics footprint. Consistent with the Project scoping exercise, no interaction between mobilisation-phase activities and the Cultural Heritage receptor has been identified. No impact is therefore expected, and this phase is accordingly scoped out.

#### 10.1.9.4.2 Exploration Drilling Operations Phase

During the drilling operations phase, the principal potential pathways of interaction with the Cultural Heritage receptor relate to the establishment of the MODU safety exclusion zone and associated support/supply vessel transfers, the drilling, wellhead and casing installation itself, the discharge of WBM fluids/cuttings and cement to the seabed and contingency activities that may include re-spudding, sidetracking, temporary well suspension, emergency disconnect, lost-circulation response and contingent cementing. Given the 8.6 km separation between Target T057 and the well location, none of these activities is expected to result in a

direct physical interaction with the target; the interactions identified are therefore precautionary in nature, reflecting the general (rather than site-specific) archaeological potential of Block 2 and the theoretical possibility of previously unidentified submerged material occurring closer to the well footprint than currently known assets. Conversely, the routine deployment of the ROV for inspection of equipment and the seabed during this phase may provide an opportunity to identify previously unrecorded material within the immediate operational area.

In summary, the negative interactions during the drilling operations phase are assessed as being of negligible intensity (IN = 1), confined to the localised project footprint given the substantial separation from Target T057 (EX = 1), immediate in onset (MO = 4), temporary and coincident with the drilling period (PE = 1), short-term and fully reversible (RV = 1), non- to lowly synergistic (SI = 1), indirect in effect given the absence of any direct interaction with a known heritage asset (EF = 1), ranging from discontinuous to continuous depending on the activity (PR = 1–4), with immediate to short-term recovery potential (MC = 1), and non-cumulative (AC = 1). Given the **High significance** of the Cultural Heritage receptor, these negligible-magnitude impacts are elevated to a final significance of **Minor**. This is consistent with the independent evaluation in the Archaeological Baseline Assessment Report (Annex 06, Section 6.4), which likewise concludes that, given the separation distance between Target T057 and the well location and the absence of any archaeological target within the 500 m assessment area, the magnitude of impact on known underwater cultural heritage is negligible and the significance of effect is negligible to minor.

| Cultural Heritage                                                                                                                                                                                     |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.9.4.3 Demobilisation and abandonment phase

During demobilisation, no interaction with known underwater cultural heritage is anticipated. Target T057 is located approximately 8.6 km from the well location, and no known cultural heritage asset has been identified within the operational footprint. No demobilisation-phase activity (cement plug installation and abandonment, MODU circulation and surface handling operations, removal of temporary subsea infrastructure, or dismantling of the onshore logistics base) has been identified as interacting with the Cultural Heritage receptor.

In summary, no impact on known underwater cultural heritage is expected during the demobilisation and abandonment phase. The post-operation ROV seabed survey around the wellhead is assessed as positive (+), of minor intensity (IN = 2), localised extent (EX = 1), immediate (MO = 4), temporary (PE = 1), short-term and fully reversible (RV = 1), non-synergistic (SI = 1), direct in effect (EF = 4), discontinuous / one-off in occurrence (PR = 1), with immediate to short-term recovery potential (MC = 1), and non-cumulative (AC = 1). In terms of overall significance, this impact is assessed as **Positive**.

| Cultural Heritage                                    |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

#### 10.1.10 Impacts on the socio-economic environment

##### 10.1.10.1 Economic Activities

This section presents the updated impact assessment for the Economic Activities VR, which has been assigned **High significance**, reflecting the Project's interaction with regional economic activities, particularly commercial fisheries, tourism, port services, logistics and local supply chains, and its potential to generate temporary employment and procurement opportunities.

Given the offshore, single-well and time-limited character of the Project, particular attention is given to marine-based economic activities, principally commercial fisheries, together with maritime tourism and aquaculture where relevant, and to the use of existing port, logistics and aviation services supporting the Project at the Port of Igoumenitsa and Corfu International Airport. Potential effects on terrestrial economic activities are also considered where they may arise through Project expenditure, procurement, employment or interaction with existing infrastructure.

##### Population and demographics

The Project is not expected to result in a material change in the population or demographic structure of the study area. The offshore location of the well and the temporary nature of the drilling campaign mean that the Project does not require land acquisition, permanent settlement, or displacement or relocation of residents in either the Corfu Regional Unit (permanent population 101,600; 2021 Census) or the

Municipality of Igoumenitsa (permanent population 25,698; 2021 Census). The use of existing port and airport facilities similarly does not require the establishment of a new permanent workforce settlement or supporting residential infrastructure.

A temporary presence of Project personnel and contractors will occur during mobilisation, drilling and demobilisation, associated primarily with the offshore drilling unit (approximately 160, with accommodation for up to 180 persons) and supporting marine and aviation logistics, rather than with a permanent increase in the resident population of the surrounding municipalities. The shore-based workforce at the Igoumenitsa logistics base is limited to approximately six personnel during routine operations. Any temporary demand generated for accommodation, food, transport and other services is therefore expected to be limited in duration and spatially concentrated around the existing logistics and service locations.

No material change in population distribution, seasonal population patterns or demographic characteristics is anticipated as a consequence of the Project. Potential indirect demographic effects associated with induced development are also not expected because the Project is a discrete exploration activity, does not establish permanent production infrastructure and does not, at this stage, provide a basis for a permanent expansion of the local economic or residential base.

Accordingly, the Project is not expected to generate a material adverse or beneficial demographic effect.

#### Local economic structure

The local economy of the wider study area comprises a combination of tourism and associated services, fisheries, port and aviation-related transport and logistics, commerce and other service-sector activities. The two areas most closely associated with the Project differ markedly in economic structure: the Corfu Regional Unit is a service-based, tourism-dependent economy (trade, transport, accommodation and food services account for 47.4% of regional GVA, and tourism is estimated to contribute approximately 75% of regional GDP), whereas the Thesprotia Regional Unit and the Municipality of Igoumenitsa host a more diversified economy in which the Port of Igoumenitsa, handling approximately 3 million passengers, 750,000 private vehicles and 350,000 trucks annually, functions as a strategic national gateway to Italy and the Adriatic. The Project does not involve permanent land take or conversion of land from existing productive uses and therefore does not directly alter the structure or spatial distribution of established terrestrial economic activities in either area.

The principal potential interaction with the local economic structure arises from the offshore nature of the Project and its interaction with existing marine users, in particular **commercial fisheries**. As set out in ESBS Section 2.6.2.3 and 2.7.4, the Asopus-1 well lies within GSA 19 (Western Ionian Sea), and although fishing intensity at the well location is lower than in coastal waters, the wider area is traversed by Greek and Italian commercial fishing vessels. The economic significance of fisheries to the two onshore study areas is modest in aggregate terms (agriculture, forestry and fishing together account for only 4.3% of Ionian Islands and 3.9% of Epirus regional GVA) but locally important for a limited number of fishing households: the most recent (2018) indicative estimate for the Corfu Regional Unit records approximately 520 registered fishing vessels and an estimated 1,560 persons engaged in the sector (boat owners and workers combined), while the “Coasts of Epirus and Kerkyra Island” fishing area recorded 807.1 tonnes of catch in 2024 (1.5% of the national total), a figure that has declined by 16.6% since 2023 and 20.2% since the 2019 peak for reasons unrelated to the Project. Notably, neither Corfu nor Igoumenitsa hosts an official fish landing market, so the economic value of locally landed catch cannot be independently verified from published statistics.

In assessing the potential interaction between the Project and commercial fisheries, the following impact pathway has been considered:

This full pathway represents the theoretical range of transmission mechanisms by which offshore hydrocarbon exploration can, in principle, generate socio-economic harm to fishing-dependent communities. Applying the Project-specific baseline evidence, however, indicates that realised effects are expected to sit toward the least severe end of this pathway. The Project comprises a single exploratory well with a conservatively assessed maximum duration of 90 days; the 500 m safety exclusion zone is small relative to the wider western Ionian fishing grounds; the Central Port Authority of Corfu has confirmed that no designated anchorage areas or permanent/seasonal fishing zones exist at the Asopus-1 location; and the pre-existing GFCM deep-water Fisheries Restricted Area already excludes bottom-contact trawling gear from the portions of Block 2 exceeding 1,000 m water depth, independently of the Project. On this basis, the pathway is not expected to progress beyond temporary, spatially confined and reversible effects on individual vessels operating in the immediate vicinity of the MODU during the drilling period, rather than a structural threat to the viability of the local fishing sector.

As set out in Section 10.1.5.2.3, while Project activities may result in temporary and localised disturbance or behavioural responses in fish, the assessment concludes that these effects are reversible and do not result in significant or long-term effects on the integrity or abundance of fish populations. Following implementation of the relevant mitigation measures, all residual impacts on fish fauna are assessed as Minor. Accordingly, the Project is not expected to cause a material reduction in fish stocks or sustained displacement of commercially exploited fish species, and any resulting secondary effect on commercial fishing activity is expected to be negligible.

Aquaculture is not expected to interact materially with the Project given its spatial concentration in coastal waters, well inshore of Block 2 (see Section 10.1.9.2).

With regard to tourism, the Corfu Regional Unit and, to a lesser extent, the Thesprotia Regional Unit constitute economically important tourism destinations within the wider study area, with, as mentioned above, tourism contributing an estimated 75% of regional GDP in the Ionian Islands Region and a smaller but growing share in Epirus (ESBS Section 2.7.5). Given that all Project infrastructure will be located or operated from locations already in established commercial or industrial use, namely the existing Port of Igoumenitsa, Corfu

International Airport, and the offshore drilling location approximately 44 km from the nearest shoreline and beyond the visual horizon of the mainland coastline, the Project is not expected to alter the physical or visual landscape upon which the region's tourism offer partly depends.

The temporary 500 m safety exclusion zone to be established around the MODU is confined to a small area of open sea situated well outside the principal recreational navigation, yachting, diving and cruise corridors identified in the maritime tourism baseline, which are concentrated in coastal and inter-island waters around Corfu, Paxos, Antipaxos, the Diapontian Islands and the Thesprotia coast. Consequently, the exclusion zone and associated support-vessel movements are not expected to restrict existing tourism-related maritime activities, and no designated bathing water, marina, dive site or tourist anchorage lies within or adjacent to the Project's offshore footprint.

As set out in Section 10.1.8.1 on seawater quality assessment, potential effects on marine water quality arising from the Project are assessed as localised, temporary and rapidly attenuating through dilution, dispersion and settling, with no measurable degradation of coastal seawater quality anticipated; overall residual impacts are assessed as Minor. No material secondary effect on the attractiveness of coastal bathing waters or reduced tourism income is therefore anticipated.

Onshore, mobilisation, drilling-support and demobilisation activities at the Port of Igoumenitsa and Corfu International Airport have the potential to generate localised noise and air emissions; however, as concluded in the air quality and noise assessments, these effects are expected to be limited in duration, confined to the immediate operational footprint of the existing port and airport, and, overall, minor and are therefore not expected to result in a discernible adverse secondary impacts on the tourism sector.

Overall, the Project is expected to generate a temporary positive stimulus to local economic activity through expenditure on logistics, marine services, port services, accommodation, catering, transport and other goods and services, concentrated principally around the Port of Igoumenitsa and, to a lesser extent, Corfu International Airport. Overall, the Project is not expected to materially alter the structure or relative importance of the established economic sectors of the study area; its principal economic effects comprise temporary interactions with marine-based activities (essentially fisheries), together with short-term expenditure and procurement benefits.

## Employment

The Project will generate employment during mobilisation, drilling and demobilisation, comprising direct employment associated with the offshore drilling campaign and supporting marine, aviation and onshore logistics activities, together with indirect employment through procurement of goods and services. The largest single workforce component is the MODU crew (approximately 160 persons typically, up to 180 accommodated), followed by support/supply vessel crews and specialist offshore contractors (drilling, cementing, well control, mud systems, ROV, marine logistics and aviation services, several of which are expected to be provided by third-party contractors). Onshore, the Igoumenitsa Supply Base is expected to employ approximately six personnel during routine operations, and helicopter operations between Corfu International Airport and the MODU are expected to generate approximately 50–60 personnel transfers per week, supporting demand for aviation and related contractor services.

At the time of the assessment, no local-hire target or percentage is specified for the 160–180-person offshore workforce, no breakdown of direct versus indirect employment is available, and the specialist nature of most offshore positions means that the availability of the relevant skills within the local labour force of

Corfu and Thesprotia has not been established. The clearest quantified local employment component remains the approximately six-person Igoumenitsa shore-based workforce, together with the more diffuse but plausible generation of local/regional employment through contracted logistics, cargo-handling, waste-management, aviation-support and other services. Given the temporary, single-well nature of the Project, employment effects are expected to be short-term rather than associated with the creation of a permanent local employment base and induced economic activity from personnel expenditure is expected to be secondary and proportionate to the limited duration and scale of the campaign.

Potential negative employment effects could principally relate to the possibility of temporary reduction in fishing effort where fishing vessels are required to avoid the Project's operational area or associated support-vessel routes; consistent with the discussion above, any such effect is expected to be temporary, localised and readily reversible upon completion of drilling, with no permanent loss of employment anticipated in the fisheries sector or other established economic sectors. Overall, the employment effect of the Project is expected to be minor positive, with a limited potential for temporary negative effects where marine economic activities (particularly fisheries) spatially and temporally overlap with the Project's operational area.

### Regional and national economy

The Project represents a temporary investment in offshore exploration and associated marine, logistics and support services within a national economy that has continued its post-pandemic recovery, with real GDP growth of 2.1% in both 2024 and 2025 and unemployment falling to 8.4% by the final quarter of 2025, its lowest level in approximately sixteen years. At the regional level, the Epirus Region and the Ionian Islands Region contributed approximately 2.0% and 1.7% of national GDP respectively in 2023 (Corfu Regional Unit 0.8%; Thesprotia Regional Unit 0.3%), so that, while the Project's expenditure is not expected to be material at the national scale, it may generate a proportionately more visible, temporary contribution to the local and regional economies through the use of existing infrastructure and services, including the Port of Igoumenitsa and Corfu International Airport, and associated marine, logistics, transport and service-sector businesses.

Because the use of existing infrastructure avoids the need for new construction, these economic benefits can be generated without the additional environmental and economic disturbance associated with development of new supporting facilities. At the national level, the Project contributes to economic activity through expenditure on specialised offshore drilling and support services and represents an investment in the exploration of Greece's offshore hydrocarbon resources; however, as an exploration campaign rather than a production development, it does not generate production revenues or the wider, long-term economic effects associated with a producing field. Any future appraisal or development activity following a successful exploration result would be subject to a separate permitting process and environmental assessment and therefore falls outside the scope of this assessment. The regional and national economic effects of the Project are accordingly expected to be positive but temporary, with their magnitude dependent on the proportion of Project expenditure and procurement retained within the Greek economy.

### Quality of life, land value and connectivity

The Project is not expected to materially affect the availability of services and facilities to the resident population of either study area. No permanent land take, residential displacement or new settlement is required, and no material pressure on housing, education, healthcare or other community services is anticipated. No material effect on land or property values is expected, given the offshore location of the well, the absence of permanent structures or land-use change, and the temporary nature of the drilling campaign.

The principal potential connectivity effect relates to temporary interactions between the Project and marine navigation and access, as follows:

These effects are expected to be temporary and localised, are addressed in detail under the Maritime Uses receptor and are not expected to result in permanent severance of established transport or economic links. Road and port movements associated with the Project may temporarily increase during mobilisation and drilling logistics, but the Project does not require new transport infrastructure or permanent changes to terrestrial connectivity. Overall, no material adverse effect on quality of life, land/property values or wider connectivity is anticipated.

#### Compatibility with other development policies and projects

The Project is a temporary offshore exploration activity that does not introduce permanent changes in land use or establish a new long-term economic activity. As set out in the compatibility assessment presented in Chapter 5 and summarised in Section 10.1.9.1 of this Chapter, the Regional Spatial Framework for Epirus (MD ΥΠΕΝ/ΔΧΩΠΣ/78523/1208, GG 286/ΑΑΠ/28-11-2018) explicitly identifies “support activities related to hydrocarbon exploration and production in the Northern Ionian and Epirus regions” among the priority functions for future diversification of the Port of Igoumenitsa, while the Regional Spatial Framework for the Ionian Islands identifies offshore hydrocarbon exploration as an activity of national economic significance, subject to environmental safeguards. The Project's use of existing port and aviation infrastructure is therefore broadly compatible with, and in the case of Igoumenitsa positively anticipated by, the strategic economic development framework applicable to the study area.

Potential interactions with other marine economic activities, including commercial fisheries, maritime transport, aquaculture and tourism, are primarily spatial and temporal in nature rather than structural, and are considered further in the cumulative and synergistic assessment where relevant. The Project does not, in itself, establish a new permanent development trajectory that would be expected to conflict with the established economic structure or development direction of the study area.

#### Overall assessment

The Project is expected to have a limited and predominantly temporary influence on economic activities within the study area. The main potential adverse pathway is associated with temporary interaction between offshore drilling/support-vessel operations and existing marine economic activities, particularly commercial fisheries, through the 500 m safety exclusion zone and associated vessel movements. Consistent with the impact pathway discussed above, this effect is expected to be localised, short-term and reversible, and does not represent a permanent loss of productive resources or a structural change in the local economy or the viability of the fishing sector.

In parallel, the Project is expected to generate temporary positive economic and employment effects through direct and indirect employment, procurement and expenditure on marine, port, aviation, transport and other support services, extending from the immediate Project area (Igoumenitsa and, to a lesser extent, Corfu) to the regional and, to a limited degree, national economy, depending on the proportion of expenditure retained within Greece. No material effects on population or demographic characteristics, permanent employment, land or property values, essential services, or long-term connectivity are anticipated, and no material incompatibility with existing development trends or strategic spatial planning objectives has been identified.

#### 10.1.10.1.1 Drilling preparation and mobilisation phase

During the mobilisation phase, interactions with the Economic Activities receptor arise principally from the recruitment and engagement of the offshore, marine and shore-based workforce, the procurement of goods and services required for the drilling campaign, the temporary occupation of quay space and staging areas within the Port of Igoumenitsa (including mobilisation and, if applicable, installation of a wharf crane), and the transit of the support vessels from their point of mobilisation to the Asopus-1 well site.

The mobilisation of the MODU and support vessels may result in temporary behavioural changes of fish in the vicinity of the vessel routes. However, these effects are spatially limited and short-term, and the associated marine fish-fauna assessment concludes that the impacts on fish fauna during the mobilisation phase are localised, reversible and of Minor significance. The mobilisation activities therefore do not result in a material reduction in the availability of fishing grounds or fish resources, and any potential secondary effect on commercial fishing activity is expected to be negligible.

The positive interactions associated with employment, procurement and expenditure on marine, port, transport and other services are expected to provide a temporary economic stimulus to the local and regional economy, principally through activities associated with the Port of Igoumenitsa.

In summary, with regard to their significance, the positive employment and procurement effects of mobilisation are assessed as of low to minor intensity (IN = 1 - 2), affecting a local to regional area (EX = 2 - 4), immediate in onset (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible on completion of the phase (RV = 1), with low to moderate synergy with concurrent port and contracting activity (SI = 1-2), largely direct in effect (EF = 1-4), discontinuous to periodic (PR = 1-2), with short-term recovery/reversion (MC = 1), and non-cumulative (AC = 1); these effects are recorded as Positive. The negative interactions associated with temporary occupation of port operational space and the offshore transit of the MODU are of negligible to low intensity (IN = 1), localised extent (EX = 1), immediate onset (MO = 4), temporary duration (PE = 1), short-term and fully reversible (RV = 1), low synergy (SI = 1), indirect effect (EF = 1), discontinuous occurrence (PR = 1), with immediate to short-term recovery (MC = 1), and non-cumulative (AC = 1). Given the High significance of the Economic Activities receptor, these negligible magnitude negative interactions are elevated to a final impact significance of Minor. Overall, impacts during the mobilisation phase are assessed as ranging from **Minor** (negative, port- and transit-related) to **Positive** (employment, procurement and local contracting).

| Economic activities                                  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.10.1.2 Exploration Drilling Operations Phase

During the drilling operations phase, the principal potential interaction with economic activities arises from the temporary establishment of the 500 m safety exclusion zone around the MODU and associated support and supply vessel movements between the Port of Igoumenitsa and the well site. These activities may require fishing vessels to maintain separation from the immediate operational area and may result in temporary localised adjustment of fishing activity where actual spatial and temporal overlap occurs. The effect is expected to be limited to the immediate vicinity of the MODU and associated vessel movements and does not represent a material reduction in the wider fishing grounds available to commercial fleets.

As set out in Section 10.1.9.2 and consistent with the ESBS baseline (Annex 02), the Asopus-1 well lies within GSA 19 (Western Ionian Sea), where the wider seascape is traversed by Greek and Italian commercial fishing vessels, although fishing intensity at the well location is lower than in coastal waters. The economic contribution of fisheries to the wider regional economies is relatively limited in aggregate terms, while remaining locally important to individual fishing households. The GFCM deep-water Fisheries Restricted Area (>1,000 m) already excludes bottom-contact fishing gear from the deeper portions of Block 2 independently of the Project, and the Central Port Authority of Corfu has confirmed that no designated anchorage areas or permanent or seasonal fishing zones are present at the Asopus-1 location.

The Project therefore does not result in the permanent loss or fragmentation of fishing grounds or a structural change to the fisheries sector. The temporary 500 m exclusion area is small in relation to the wider fishing grounds, and any effect on individual fishing activity will depend on the extent to which vessels would otherwise have operated within the immediate Project area during the drilling campaign. Consequently, the potential economic effect is expected to be limited principally to temporary localised displacement or adjustment of individual fishing activity, with access to the area restored following completion of drilling and departure of the MODU.

Other drilling-related activities, including drilling, wellhead and casing installation, VSP activities and the various controlled discharges associated with drilling operations, are not expected to result in material direct effects on economic activities. Any potential interaction with fisheries would arise indirectly through temporary and localised changes in fish behaviour, availability or environmental conditions, rather than through loss of fishing grounds or direct restriction of access. As set out in Sections 10.1.5.2.3 and 10.1.8.1, the residual effects on marine fish fauna and seawater quality are assessed as Minor and are not expected to result in significant or long-term effects on fish populations, fish-stock condition or the wider marine environment. Accordingly, no more than negligible secondary effects on commercial fishing through changes in fish-stock availability or sustained displacement of commercially exploited species are anticipated.

In parallel, the continued operation of the Igoumenitsa logistics base, the deployment of helicopter services between Corfu International Airport and the MODU, and sustained Project expenditure on marine, port, aviation, catering, transport and waste-management services throughout the drilling campaign are expected to generate a positive, if temporary, economic stimulus to the local and regional economy, concentrated principally around Igoumenitsa.

In summary, with regard to their significance, the principal adverse interaction with economic activities during the drilling operations phase is the temporary and localised displacement or adjustment of commercial fishing activity associated with the MODU safety exclusion zone and support-vessel movements. It is assessed as of low intensity (IN = 1), local extent (EX = 2), immediate onset (MO = 4), temporary and coincident with the drilling campaign (PE = 1), short-term and fully reversible on cessation of drilling (RV = 1), with limited interaction with concurrent marine uses (SI = 1), and predominantly secondary in economic effect (EF = 1). The effect is periodic rather than continuously realised for individual fishing operators, reflecting that an economic effect would arise only where fishing activity overlaps spatially and temporally with the Project operational area (PR = 2). Recovery is expected to be short-term (MC = 1), and the effect is non-cumulative (AC = 1), yielding a negligible magnitude that, given the High significance of the receptor, is elevated to Minor in the final impact significance.

Discharge- and drilling-related effects are indirect secondary effects on fishing activity and are assessed as of negligible magnitude and Minor significance.

The positive interactions associated with logistics base operation, aviation services, employment, procurement and continued Project expenditure remain temporary positive effects.

Overall, impacts on Economic Activities during the drilling operations phase are therefore assessed as predominantly **Minor** for the adverse interactions, with **Positive** effects arising from Project employment, procurement and expenditure. The assessment does not identify a material reduction in fishing grounds, fish-stock availability or sustained displacement of commercially exploited species, and no material adverse effect on the long-term viability of commercial fisheries or the wider economic structure of the study area is anticipated.

### 10.1.10.1.3 Demobilisation and abandonment phase

Demobilisation activities involve the removal of the 500 m safety exclusion zone and any temporary subsea infrastructure, the removal, retention or transfer, as agreed with the relevant facility operator, of the temporary logistics base from the Port of Igoumenitsa, and the removal, retention or transfer, as agreed with the relevant facility operator, of the temporary helicopter hangar from Corfu International Airport. With the exception of the residual, negligible interaction associated with waste contractor collections during decommissioning of the shore base, these activities are uniformly associated with the restoration of unrestricted marine access (including for commercial fishing) and the release of port and airport operational space back to routine business.

In summary, with regard to their significance, the removal of the exclusion zone and temporary facilities is assessed as positive (+), of minor intensity (IN = 1), localised extent (EX = 1), immediate in onset (MO = 4), temporary in duration (PE = 1), short-term and fully reversible (RV = 1), non- synergistic (SI = 1), indirect in effect (EF = 1), discontinuous (PR = 1), with short-term recovery/restoration potential (MC = 2), and non-cumulative (AC = 1); these effects are recorded as Positive. The residual negative interaction associated with waste contractor collections is of negligible magnitude and Minor significance. Overall, the demobilisation and abandonment phase is assessed as predominantly **Positive** for the Economic Activities receptor, reflecting the restoration of full, unrestricted use of the marine area, the port and the airport to their pre-Project condition.

| Economic activities                        |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.10.2 Community Health and Safety (H&S)

Community H&S is not a criterion of MD oik. 170225/2014 Annex 2; it is included as a supplementary receptor, consistent with international good industry practice, alongside socio-economic criteria. The assessment is limited to effects on third parties external to the Project workforce (other maritime users, aviation users, road users near the Port of Igoumenitsa and Corfu International Airport, and the wider public). Occupational H&S of the Project's own workforce is managed through Energean's and its contractors' OHS Management Systems and is not assessed here.

In assessing the potential interaction between the Project and with H&S of third parties and nearby communities the following impact pathways have been considered:

As set out in Table 10-1, Community H&S has been assigned **High significance** as a Valued Receptor, reflecting the importance of protecting third parties rather than an expectation of significant adverse effects. Major-accident consequences are addressed separately in Section 10.2 and are not duplicated here; detailed air quality, noise, waste and transport assessments are in Sections 10.1.6, 10.1.7.1, 10.1.10.4 and the Waste Management Plan (Annex 04), Chemical Use Plan (Annex 05), Shipping and Navigation Assessment (Annex 07) and Onshore Traffic Management Plan (Annex 08).

#### 10.1.10.2.1 Drilling preparation and mobilisation phase

During drilling preparation and mobilisation, interactions with Community H&S arise principally from temporary increases in vehicle, lifting and cargo-handling activity at the Port of Igoumenitsa, establishment of temporary facilities, installation of the temporary helicopter hangar at Corfu International Airport, and mobilisation of the MODU and support vessels. These activities take place within existing operational port, airport and marine environments and are subject to established site, port, airport and maritime safety procedures, together with the Onshore Traffic Management Plan (Annex 08) and the navigational controls described in Section 10.1.9.1.2.

The resulting interaction with third parties is expected to be limited and localised. Temporary increases in traffic and lifting activity may require routine coordination with other port and airport users, but do not require permanent changes to access arrangements or the introduction of new public infrastructure. Signage and

directional markings provide a minor beneficial interaction by improving traffic segregation and site safety. Overall, the mobilisation activities are expected to result in predominantly negligible to low-magnitude, temporary and reversible effects on Community H&S, with the principal potential interaction associated with the temporary presence and movement of the MODU and support vessels.

In summary, with regard to their significance, the impacts on Community H&S during the mobilisation phase are assessed as predominantly negative (-), of negligible intensity (IN = 1), localised in spatial extent (EX = 1-2), occurring immediately upon commencement of the relevant activity (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with low synergistic interaction with concurrent port, airport and vessel-traffic activities (SI = 1 - 2), direct in effect (EF = 4), discontinuous in occurrence (PR = 1), with immediate to short-term recovery potential (MC = 1), and non-cumulative (AC = 1). Given the High significance of the Community H&S receptor, these negligible magnitude impacts are elevated to a final significance of **Minor**. The installation of signage and directional markings is assessed as a beneficial interaction and recorded as Positive.

| Community H&S                                                         |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

#### 10.1.10.2.2 Exploration Drilling Operations Phase

During the drilling operations phase, Community H&S interactions principally concern continuous support/supply vessel movements and the temporary 500 m safety exclusion zone, helicopter transfers between Corfu International Airport and the MODU, chemical handling in accordance with the Chemical Use Plan (Annex 05), high-pressure testing of the MODU blowout preventer, the use and storage of sealed radioactive sources for LWD/wireline logging, ongoing chemicals and waste management at the onshore

logistics base, and the continued operation of onshore facilities, equipment and vehicles at the Port of Igoumenitsa.

The principal direct Community H&S pathway is associated with the temporary interaction of Project vessels and the safety exclusion zone with other marine users. This interaction is managed through the embedded maritime safety controls described in Section 10.1.9.1.2 and Annex 09, including RAM status, 24/7 watchkeeping, AIS/ARPA monitoring, appropriate navigation lights and shapes, the 500 m safety zone, NAVTEX and Notices to Mariners. The independent Formal Safety Assessment concludes that the residual shipping and navigation risk is Broadly Acceptable (ALARP). The temporary nature of the Project, the defined operational area and the established communication and navigational controls limit the potential for adverse effects on third-party safety.

Other offshore activities have substantially more limited Community H&S pathways. Handling of pipe dope and well-control chemicals, together with testing of the MODU blowout preventer, is subject to established operational and occupational H&S controls. Given the offshore location of the MODU and the absence of public access to the facility, these activities do not create a material community exposure pathway and are therefore assessed as Minor.

The use and storage of sealed radioactive sources for LWD/wireline logging, together with their onshore storage and transport, is subject to EEAE licensing and the applicable Radiation Safety Manual controls. The sources are fully encapsulated and are not released to the environment. They are sealed and managed in accordance with applicable EEAE licensing requirements and radiation-safety procedures. In the absence of public access to the MODU and with controlled onshore handling and transport, the potential for third-party exposure is negligible. These activities are therefore assessed as Minor rather than as a material community-level H&S impact.

Onshore, logistics-base chemical and waste management, presents a temporary interaction with port workers and other port users. These activities are managed through the Chemical Use Plan (Annex 05), Waste Management Plan (Annex 04) and applicable port procedures. The interaction is expected to remain localised and low intensity, with no material change to the established function or safety arrangements of the Port of Igoumenitsa.

Operation of facilities, equipment and vehicles at the logistics base represents a mixed interaction. Routine vehicle and equipment movements introduce a limited additional interaction with other port users, while implementation of the Onshore Traffic Management Plan (Annex 10), trained personnel and coordination with the Port Authority provide a beneficial safety-management function. The overall interaction is therefore retained as Positive.

Drilling contingency activities are non-routine and require enhanced safety controls. Their potential Community H&S interaction is nevertheless limited by the offshore location of the MODU, the absence of public access to the operational area and the application of dedicated emergency and well-control procedures. They are therefore assessed as Minor.

Helicopter transfers between the heliport and the MODU are expected to result in only a negligible interaction with third parties, given established aviation safety procedures, defined flight arrangements and the limited frequency of movements. These remain Minor.

Routine offshore air emissions and noise are not expected to result in material exposure of nearby communities because of the offshore location of the MODU and the distance from the nearest shoreline. These aspects are assessed separately in Sections 10.1.6 and 10.1.7.1.

In summary, with regard to their significance, the impacts on Community H&S during the drilling operations phase are predominantly negative, of negligible to low intensity (IN = 1–2), localised to the immediate operational footprint or the vessel/helicopter transit corridors (EX = 1), immediate in onset (MO = 4), temporary and coincident with the drilling campaign (PE = 1), short-term and fully reversible (RV = 1), with low to moderate synergistic interaction with concurrent port, maritime and aviation activity (SI = 1–2), predominantly limited or indirect in effect for community receptors (EF = 1), discontinuous given the potential for third-party exposure / interaction (PR = 1), with short-term recovery potential (MC = 1), and non-cumulative (AC = 1).

Given the High significance of the Community H&S receptor, the resulting impacts are **Minor** because their potential community-level exposure is limited, controlled and localised. The routine operation of onshore facilities, equipment and vehicles remains recorded as **Positive** where the safety-management and traffic-coordination measures provide a beneficial interaction with community safety.

| Community H&S                                                                                                                 |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |

### 10.1.10.2.3 Demobilisation and Abandonment Phase

During demobilisation, Community H&S interactions are limited to the routine collection and transport of remaining waste streams by licensed contractors (in accordance with the Waste Management Plan, Annex 04) and to the removal, retention or transfer, as agreed with the relevant facility operator, of the temporary logistics base and helicopter hangar. Waste contractor collections involve a temporary, low-intensity increase in heavy-vehicle movements within and around the Port of Igoumenitsa and standard hazardous-waste transport documentation and controls. The cessation of Project activities will remove the associated temporary interaction with other facility users.

In summary, with regard to their significance, waste contractor collections during demobilisation are assessed as negative (-), of negligible intensity (IN = 1), localised extent (EX = 1), immediate (MO = 4), temporary (PE = 1), short-term and fully reversible (RV = 1), non synergistic (SI = 1), indirect (EF = 1), discontinuous in occurrence (PR = 1), with immediate recovery potential (MC = 1), and non-cumulative (AC = 1); given the High significance of the Community H&S receptor, this impact is assessed as **Minor**. The cessation of Project use of the logistics base and helicopter hangar are assessed as **positive**.

| Community H&S                              |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |                     |

### 10.1.11 Social infrastructure

The assessment of potential impacts on social infrastructure considers the potential for Project activities to affect the capacity, accessibility and functioning of existing health, social protection and educational services

within the study area. In particular, it considers whether the Project could generate additional demand for existing services or restrict access to established social infrastructure

As established in the ESBS (Annex 02), the study area is served by an established network of social infrastructure operating at local, regional and national levels. Healthcare provision comprises primary healthcare facilities, regional hospitals and specialised referral centres, including the General Hospital of Corfu and the University Hospital of Ioannina, supported by local health centres and regional clinics in the Municipality of Igoumenitsa and the Regional Unit of Corfu. Social protection services are provided through regional Social Welfare Centre branches and other public social care units, while educational infrastructure includes established networks of kindergartens, primary and secondary schools, together with higher education provision through the Ionian University and the University of Ioannina.

The Project will use existing health and emergency services only incidentally and does not require the provision of new or expanded social infrastructure. The Project does not introduce a permanent resident population, require resettlement, or result in a sustained increase in demand for healthcare, social protection or educational services. Any use of existing public health or emergency services would therefore be occasional and associated principally with unforeseen circumstances rather than routine Project demand.

During the drilling preparation and mobilisation phase, temporary Project personnel and contractors will be present at the Port of Igoumenitsa and Corfu International Airport, while mobilisation activities take place within existing operational areas. The temporary increase in personnel associated with these activities is not expected to generate material additional demand for local healthcare, emergency, social protection or educational services. The activities are short-term and will not alter the capacity or accessibility of existing social infrastructure.

During the exploration drilling operations phase, the majority of Project personnel will be associated with the offshore MODU and marine support activities, with additional personnel supporting the logistics base and helicopter operations. The Project will continue to rely on existing regional healthcare and emergency-service infrastructure where required, but no material increase in routine service demand is anticipated. The temporary nature of the drilling campaign, the limited Project workforce relative to the wider population served by the existing infrastructure, and the implementation of Project-specific emergency and OHS arrangements mean that any additional demand on existing services is expected to be negligible. The offshore location of the MODU also means that the Project does not create a permanent demand for local schools, social care facilities or other community-based social infrastructure.

During demobilisation and abandonment, Project personnel and contractors associated with the temporary logistics and marine operations will be progressively demobilised and temporary facilities removed. This will further reduce any potential temporary demand generated by the Project, with no residual requirement for social infrastructure following completion of the exploration programme.

Overall, the Project is not expected to affect the capacity, accessibility or functioning of existing health, social protection or educational infrastructure. Any use of existing services will be incidental, temporary and associated principally with individual or unforeseen circumstances rather than a material increase in routine demand. The Project does not require new or expanded social infrastructure, does not introduce a permanent population, and does not result in restrictions on access to existing services.

The Social Infrastructure Valued Receptor is therefore considered to be of **Low significance**. Given the absence of a permanent Project-related population, the limited and temporary workforce, the incidental

nature of Project reliance on existing services, and the lack of anticipated increase in demand or restriction of access, the receptor is **scoped out** of further detailed impact assessment.

## 10.1.12 Impacts on technical infrastructure

### 10.1.12.1 Maritime infrastructure

#### 10.1.12.1.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, potential impacts on maritime transport infrastructure will be associated with the temporary use of the Port of Igoumenitsa as the Project logistics base, mobilisation of the MODU to the offshore well location, and initial support vessel movements. The Port of Igoumenitsa is a major national port and a key maritime gateway for domestic and international ferry, Ro-Ro, freight and passenger traffic, including routes to Corfu, Lefkimmi, Paxoi, Patras and Italian Adriatic ports. As a result, Project activities may temporarily interact with existing port operations, berth use, cargo handling areas, internal port circulation and vessel traffic approaching or departing the port.

Potential effects during mobilisation may include short-term and localised increases in vessel traffic, loading and unloading activity, use of quay space, and coordination requirements with existing ferry and freight movements. These effects will occur within an already operational port environment designed to accommodate intensive maritime and logistics activity. No new port infrastructure, dredging, reclamation, quay modification or permanent alteration of maritime transport infrastructure will be required.

Offshore, the transit of the MODU and support vessels to the well location may temporarily interact with established maritime traffic routes in the northern Ionian Sea, including the dense Corfu-mainland corridor and broader ferry and commercial navigation routes linking Greece with Italy. These interactions will be managed through standard maritime safety procedures, navigational warnings, coordination with competent authorities and compliance with port and navigation requirements.

In summary, with regard to their significance, the impacts on maritime transport infrastructure during the mobilisation phase are assessed as negative (-), with low intensity (IN = 2), localised (EX = 2), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in **Chapter 11** of this ESIA, **residual impacts** are assessed as **minor**.

| Impacts on maritime transport infrastructure         |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |                     |                              |

| Mobilisation of MODU to well site – power generation | -          | 2              | 2           | 4           | 1                | 1                  | 2            | 4           | 1                | 2             | 1                 | 26 Low                | High                       | MODERATE            | MINOR                        |

#### 10.1.12.1.2 Exploration drilling operations phase

During the exploration drilling operations phase, impacts on maritime transport infrastructure will arise mainly from routine support vessel movements between the Port of Igoumenitsa and the MODU, the presence of the MODU at the offshore drilling location, and the establishment of the temporary 500 m safety zone. The safety zone will temporarily restrict access to a small area around the drilling unit and may require passing vessels, including commercial or fishing vessels, to maintain safe separation from the MODU.

The Project will not physically affect port infrastructure, ferry terminals, navigation channels, port approaches or established shipping lanes. The Port of Igoumenitsa will continue to operate as a major transport node, and Project-related vessel movements are expected to represent only a minor addition to the existing level of maritime traffic associated with domestic ferries, international Adriatic routes, freight and Ro-Ro operations. Similarly, the Corfu-Igoumenitsa ferry corridor and the main port approaches to Corfu and Igoumenitsa are not expected to be materially affected.

Potential impacts may include temporary increases in vessel traffic, additional coordination requirements for port entry and departure, and minor route awareness requirements for vessels operating in the vicinity of the offshore safety zone. These effects will be managed through Notices to Mariners, NAVTEX or equivalent navigational communications, liaison with port authorities, vessel traffic coordination and adherence to maritime safety procedures.

Potential impacts on port infrastructure would therefore relate mainly to temporary operational demand rather than physical effects. These may include additional berth use, vessel turnaround, loading and unloading of supplies, temporary laydown of materials, waste transfer, logistics coordination, and use of existing port access and support services. No new port infrastructure, dredging, quay modification or permanent change to port facilities is anticipated.

According to the traffic and navigation assessment (**Annex 09**), impacts from Project vessels within port limits, including transit to and from Igoumenitsa, are assumed to be managed by the ports themselves. Accordingly, any routine interaction with port infrastructure is expected to be managed through standard port authority procedures, berth allocation, vessel scheduling, port traffic management and compliance with applicable maritime requirements.

In summary, with regard to their significance, the impacts on maritime transport infrastructure during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN = 1 – 2), localised (EX=2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing maritime transport operations (SI=2), direct (EF=4), irregular (movement of support vessels) or continuous (PR = 1 – 4), with immediate recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in **Chapter 11** of this ESIA, **residual impacts** are assessed as **minor**.

| Impacts on maritime transport infrastructure                   |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |                     |                              |

### 10.1.12.1.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, impacts on maritime transport infrastructure will be associated with departure of the MODU and support vessels from the well location, return of equipment and materials to the Port of Igoumenitsa, and removal, retention or asset transfer, as agreed with the relevant facility operator, of temporary shore base facilities. This phase may generate a short-term increase in vessel movements, unloading operations and logistics activity at the port, similar in nature to the mobilisation phase.

Potential interactions may occur with ferry, freight, Ro-Ro and passenger services at Igoumenitsa, particularly if demobilisation activities coincide with periods of high port traffic or seasonal tourism demand. However, these interactions will be temporary and operational in nature and will be managed through port scheduling, berth coordination, designated loading and unloading areas, and communication with the competent port authorities.

During dismantling works and removal of temporary Project facilities from the port area, minor short-term adverse effects may occur due to vehicle movements, lifting operations, waste collection, temporary occupation of working areas and potential interaction with normal port traffic. These effects will be localised, temporary and managed through port coordination, designated access routes, appropriate scheduling and standard health, safety and environmental controls. At the same time, the removal of temporary offices, storage areas, equipment, signage and support facilities will release occupied space and restore the affected port areas to their normal operational use. This will have a minor positive effect on port operations by reducing temporary congestion, removing Project-related constraints and returning port circulation and logistics areas to baseline conditions.

No permanent modification of maritime transport infrastructure will be required. Following completion of demobilisation, Project-related vessel traffic and port logistics will cease, and maritime transport conditions will return to baseline port operations.

In summary, with regard to their significance, the impacts on maritime transport infrastructure during the demobilisation / abandonment phase are assessed as negative (-), with negligible intensity (IN = 1),

localised (EX = 2), occurring immediately during demobilisation activities (MO = 4), coincident with the demobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **moderate**. Following the implementation of prevention and mitigation measures described in **Chapter 11** of this ESIA, **residual impacts** are assessed as **minor**.

| Impacts on maritime transport infrastructure |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |                              |

#### 10.1.12.2 Other transport infrastructure

##### 10.1.12.2.1 Drilling preparation and mobilisation phase

During the drilling preparation and mobilisation phase, potential impacts on road traffic infrastructure will be associated with the transport of equipment, materials, containers, consumables and personnel to the temporary shore base within the Port of Igoumenitsa, as well as limited preparatory activities at Corfu International Airport, where applicable. The main road interaction will occur in the Igoumenitsa area, particularly along the access routes connecting the port with the Egnatia Odos motorway, the Preveza-Igoumenitsa National Road and the local road network serving the port zone.

The additional Project-related vehicle movements are expected to be temporary and limited in scale compared with the existing traffic associated with the Port of Igoumenitsa, ferry operations, commercial logistics and local urban mobility. No new road infrastructure, road widening or permanent modification of the road network will be required. Potential effects may include short-term increases in heavy goods vehicle movements, minor delays at port access points, and temporary pressure on internal port circulation areas during equipment delivery and staging.

The effects on local road network will be managed through logistics planning, use of designated port access routes, scheduling of deliveries and coordination with port authorities.

The installation of temporary signage and directional markings during mobilisation is expected to have a minor positive impact on road traffic infrastructure and internal port circulation. These measures will improve the organisation of vehicle movements within the shore base and port area, support safe access to loading, unloading and storage zones, and reduce the potential for vehicle conflicts, delays or inefficient routing. The positive effect will be localised and temporary, but beneficial for traffic management, occupational safety and coordination of logistics activities during the Project.

In summary, negative (–) impacts on transport infrastructure during the mobilisation phase are assessed as having low intensity (IN = 2), localised (EX = 2), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), synergistic (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **minor**.

| Impacts on transport infrastructure      |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

#### 10.1.12.2.2 Exploration drilling operations phase

During the exploration drilling operations phase, road traffic impacts will be mainly associated with routine shore base support activities, including delivery of supplies, movement of personnel, transfer of waste to licensed contractors, and occasional transport of equipment or materials between the port and authorised facilities.

Road movements related to the Project will take place within an area already served by established port access roads and the wider regional road network. The Port of Igoumenitsa is served by established road connections, including direct access to the Egnatia Motorway and the Igoumenitsa–Preveza National Road, while the Igoumenitsa Ring Road provides an alternative route that allows traffic to bypass the city centre. These roads are designed to support port-related transport and commercial vehicle movements.

Existing port traffic is already organised through separate access gates for international ferry, domestic ferry and cruise traffic, reducing potential conflicts between different vehicle types and users. The Project will not require abnormal continuous road traffic volumes, road closures or changes to the functional role of existing roads. Any additional traffic will be absorbed within the normal operational context of the port and surrounding transport network.

The surrounding road network is considered to have sufficient available capacity to accommodate port-related traffic. The practical capacity of the external port road has been conservatively estimated at approximately 2,500 Passenger Car Units (PCU) per hour, while even a high-demand scenario involving the simultaneous arrival of a domestic ferry and cruise ship would generate approximately 1,260 PCU per hour. Under this scenario, the network would continue to operate within available capacity and without significant congestion.

Vehicle movements due to Project operation are expected to be low compared with existing port activity. Traffic associated with establishing storage facilities, onloading and offloading from exploration vessels, customs arrangements and parking is not expected to require significant vehicle movements. During

operations, traffic will mainly comprise logistical support, waste management and servicing, equipment deliveries, staff access, forklifts, flatbed trucks, mobile cranes and pickup trucks, with most movements occurring within the port supply-base area.

Potential impacts on road transport infrastructure would therefore relate mainly to temporary increases in local vehicle movements within and around the port, possible short-term interactions with existing ferry and port traffic, and limited risk of driver delay or traffic conflicts. No road widening, new public road infrastructure, permanent alteration to the highway network or long-term reduction in road capacity is anticipated.

Potential impacts may include minor increases in heavy vehicle movements near the port, temporary interaction with ferry-related traffic peaks, and limited additional demand on internal port circulation areas.

The effects on local road network will be managed through coordinated logistics planning, avoidance of unnecessary vehicle movements, use of approved transport contractors and compliance with port traffic management procedures. The implementation of a Traffic Management Plan will further reduce potential impacts by defining traffic management responsibilities, managing vehicle movements, reducing traffic-related hazards, and applying monitoring and compliance procedures.

Helicopter transfers between Corfu International Airport and the MODU will interact with existing airport infrastructure through the use of established aviation facilities, including the heliport or designated helicopter operating area, air traffic control services, refuelling arrangements, passenger handling procedures, security controls and emergency response capacity. The transfers will support crew changes, personnel movements, urgent logistics and, if required, emergency response functions during the offshore drilling campaign.

The Project is expected to involve a limited number of helicopter flights per week, using a medium twin-engine helicopter such as an AW139 or equivalent. This level of activity is minor in comparison with the normal operational capacity of Corfu International Airport, particularly as the airport already supports commercial aviation, general aviation, emergency services and seasonal tourism-related air traffic. Therefore, no expansion, upgrade or permanent modification of airport infrastructure is expected to be required.

Potential impacts may include a temporary and limited increase in helicopter movements, use of apron or heliport space, minor additional demand on aviation fuel supply, passenger processing and coordination with airport operational services. These effects will be operational in nature and will be managed through standard airport procedures, flight scheduling, air traffic control coordination, aviation safety requirements and emergency preparedness arrangements.

During peak tourism periods, helicopter transfers may coincide with higher airport activity. However, the number of Project-related flights will remain limited and can be scheduled to avoid operational conflicts where practicable. As a result, no significant effect on airport capacity, runway operations, passenger services, safety systems or airport infrastructure is anticipated.

In summary, with regard to their significance, the impacts on transport infrastructure during the drilling operations phase are assessed as negative (-), of negligible to low intensity (IN = 1 – 2), localised (EX=2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing transport operations (SI=2), direct

(EF=4), periodic (helicopter transfers) or continuous (PR = 2 – 4), with immediate recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

#### 10.1.12.2.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, road traffic impacts will arise from the removal of equipment, temporary facilities, materials and waste from the Port of Igoumenitsa, together with waste contractor collections and transport of residual materials to authorised facilities. This phase may generate a short-term increase in heavy vehicle movements, similar in nature to the mobilisation phase, but limited in duration.

The main affected areas will be the internal port road network, port access roads and connections to the Egnatia Odos and national road network. No permanent changes to road infrastructure will be required. Potential effects may include temporary congestion at port access points, increased heavy vehicle circulation within the port area, and short-term interaction with ferry, commercial and tourism-related traffic.

The effects on local road network will be managed through coordination with port authorities, scheduling of vehicle movements, use of designated loading and access areas, and prompt removal of materials and waste from the shore base.

Following completion of demobilisation, Project-related road traffic will cease, and traffic conditions will return to baseline port operation.

In summary, with regard to their significance, the impacts on transport infrastructure during the demobilisation / abandonment phase are assessed as negative (-), with negligible intensity (IN = 1), localised (EX = 2), occurring immediately during demobilisation activities (MO = 4), coincident with the demobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on transport infrastructure        |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

### 10.1.12.3 Energy, telecommunications

#### 10.1.12.3.1 Drilling preparation and mobilisation phase

During the mobilisation phase, limited temporary demands will arise from the establishment of the shore base within the Port of Igoumenitsa, including connection of temporary offices, lighting, welfare facilities and communications equipment. These requirements will be met through existing port electricity distribution infrastructure and local telecommunications networks, which are already integrated into the wider interconnected Greek transmission and distribution system operated by ADMIE/IPTO and PPC S.A.

The additional electrical load associated with mobilisation activities is expected to be small, short-term and well within the available capacity of the existing low- and medium-voltage distribution network serving the port area. No reinforcement of transmission-level infrastructure is anticipated.

Telecommunications demand will be limited to standard operational communications, data transfer, and coordination between offshore and onshore teams. Existing fixed-line, mobile and broadband networks within Igoumenitsa and the wider Epirus region are well developed, and no significant capacity constraints are expected.

No impacts are anticipated on natural gas infrastructure, as the Project will not connect to or utilise the national gas transmission system.

In summary, with regard to their significance, the impacts on energy and telecommunications infrastructure during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on energy and telecommunications infrastructure |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |            |                            |                     |
|---------------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|------------|----------------------------|---------------------|
| Project Activities / Elements                           | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |            | Valued Receptor Assessment | Impact Significance |
| Onshore base equipment and utilities installation       | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20                    | Negligible | Low                        | NEGLECTIBLE         |

### 10.1.12.3.2 Exploration drilling operations phase

During offshore drilling operations, the principal energy demand will be associated with the MODU and support vessels, which will be covered by on board systems, and will not rely on shore-based electricity generation or distribution networks. Consequently, there will be no direct demand on the local electricity transmission system arising from offshore drilling activities.

The shore base will operate using existing port electricity and telecommunications infrastructure for administrative functions, logistics coordination, waste management activities, and routine operational communications. These demands are expected to remain minor in the context of the overall capacity of the Igoumenitsa port electrical network and regional distribution system.

Telecommunications infrastructure will be used for offshore–onshore coordination, including operational monitoring and logistics. The national mobile and broadband networks in the region have sufficient capacity to accommodate these temporary Project requirements. Therefore, no significant effects on telecommunications infrastructure are anticipated.

Within the logistics base area, minor and intermittent increases in electricity demand may occur due to cargo handling equipment, lighting, and temporary storage operations. However, these activities are short-duration and dispersed and will not materially affect regional energy infrastructure.

No interaction is expected with natural gas infrastructure, which is not present in the immediate project area.

In summary, with regard to their significance, the impacts on energy and telecommunications infrastructure during the drilling operations phase are assessed as negative (-), of negligible intensity (IN=1), localised (EX=2), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing port operations (SI=2), direct (EF=4), continuous (PR=4), with immediate recovery after completion of drilling (MC=1), and non-cumulative (AC=1). Overall, these impacts are assessed as **negligible**.

| Impacts on energy and telecommunications infrastructure  |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |  |
|----------------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|-----|----------------------------|---------------------|--|

### 10.1.12.3.3 Demobilisation and Abandonment Phase

During demobilisation, energy and telecommunications demands at the shore base will gradually reduce as equipment is dismantled and materials are removed. Electricity use will be mainly for waste handling, lifting operations, container loading, and equipment disassembly activities; however, these are short-term and occur within the existing capacity of port infrastructure.

All waste contractor activities, including vehicle movements, container handling and loading operations, will be supported by existing port utilities without requiring upgrades or extensions to the electricity distribution network.

Telecommunications usage may temporarily increase during coordination of logistics, waste transfer documentation, and reporting requirements associated with site closure; however, this remains well within normal operational usage patterns of the port and municipal communication systems.

Following completion of demobilisation, all temporary facilities will be removed, and energy and telecommunications demand will return to baseline port conditions.

In summary, with regard to their significance, the impacts on energy and telecommunications infrastructure during the demobilisation / abandonment phase are assessed as negative (–), with negligible intensity (IN = 1), localised (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the demobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on energy and telecommunications infrastructure |            |                |             |             |                  |                    |             |             |                  |               |                   |                       |            |                            |                     |

| Dismantling and removal from the port area              | -          | 1              | 1           | 4           | 1                | 1                  | 1           | 4           | 1                | 2             | 1                 | 20                    | Negligible | Low                        | NEGLIGIBLE          |

#### 10.1.12.4 Environmental infrastructure

Environmental infrastructure receptors comprise the existing municipal and port infrastructure serving the Port of Igoumenitsa, including waste collection, transfer and disposal systems, port reception facilities for ship-generated waste and wastewater management facilities.

##### 10.1.12.4.1 Drilling preparation and mobilisation phase

Activities during this phase will include mobilisation of equipment and materials, loading and unloading operations, warehousing and storage activities, office and logistics support, and preparation of supplies for offshore transfer. Interactions with the existing environmental infrastructure of Igoumenitsa will be limited to the temporary use of the Port of Igoumenitsa shore base and associated municipal waste and wastewater management services.

Waste generated during mobilisation will consist primarily of packaging materials (paper, cardboard, wood and plastics), small quantities of scrap metal, domestic-type wastes from shore base personnel, and limited quantities of hazardous wastes associated with equipment preparation and maintenance activities, such as waste oils, lubricants, used absorbents and empty chemical containers. Based on the indicative waste estimates (Table 6.23), approximately 2.3 tonnes of non-hazardous waste may be generated during the mobilisation period.

These waste streams will be segregated, temporarily stored within designated areas at the shore base, and subsequently collected by authorised waste contractors.

During the mobilisation phase, waste generated from logistics, equipment preparation and shore base activities will be segregated and managed through the Project's dedicated Waste Management System. Offshore waste returned to shore and waste generated at the supply base will be temporarily staged before being transferred by licensed contractors to authorised treatment, recovery or disposal facilities. The quantities of waste generated during mobilisation will be relatively small, the shore-based workforce will be limited, and the activities will be temporary. As a result, the additional demand on existing licensed waste management facilities serving the Igoumenitsa area is expected to be negligible. No expansion of existing waste management infrastructure or construction of new waste handling facilities will be required. Consequently, impacts on the existing environmental infrastructure are expected to be localised, short term and of negligible significance.

In summary, with regard to their significance, the impacts on environmental infrastructure during the mobilisation phase are assessed as negative (-), with negligible intensity (IN = 1), localised (EX = 1), occurring immediately during mobilisation activities (MO = 4), coincident with the mobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on environmental infrastructure           |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |
|---------------------------------------------------|------------|----------------|-------------|-------------|------------------|--------------------|--------------|-------------|------------------|---------------|-------------------|-----------------------|----------------------------|
| Project Activities / Elements                     | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) | Valued Receptor Assessment |
| Onshore base equipment and utilities installation | -          | 1              | 1           | 4           | 1                | 1                  | 1            | 4           | 1                | 2             | 1                 | 20 Negligible         | Medium NEGLIGIBLE          |

#### 10.1.12.4.2 Exploration Drilling operations phase

Offshore drilling activities will generate several waste streams that cannot be discharged to the marine environment and will therefore require controlled collection, temporary storage, transport and subsequent treatment, recovery or disposal through authorised onshore facilities. These waste streams are expected to include municipal solid waste from accommodation and catering activities on the MODU and support vessels, hazardous and operational wastes arising from drilling and maintenance activities, such as waste oils and oily residues, electrical and electronic equipment waste, used cooking oil, spent chemicals, contaminated absorbents, filters, paint residues, empty chemical containers and other maintenance-related materials.

Based on available estimates, offshore operations are expected to generate approximately 1.2 tonnes of general non-recyclable waste, 1.5 tonnes of paper, wood and cardboard, 2.35 tonnes of metals, 375 kg of electrical waste and 75 kg of used cooking oil over the drilling campaign. Hazardous waste is estimated to include approximately 29 m<sup>3</sup> of oily sludge, 4.6 tonnes of oil-contaminated waste, 1.4 tonnes of paints and solvents, and 7.2 tonnes of chemical waste (Table 6.22). In addition, onshore operations are expected to generate approximately 1.3 tonnes of general non-recyclable waste, paper, 1.6 tonnes of wood and cardboard, 80 kg of plastic, 1.7 tonnes of metal and 600 kg of food waste (Table 6.23).

Where logging-while-drilling (LWD) results indicate the presence of hydrocarbons, or where cuttings become contaminated due to drilling through hydrocarbon-bearing formations or operational upsets, such materials will not be discharged to sea. Instead, they will be recovered using onboard containment systems such as skips or vacuum transfer units, securely stored, and subsequently transferred to shore for treatment and disposal at licensed facilities.

All wastes will be managed under the Project's Waste Management System, which ensures segregation at source, controlled storage onboard the MODU and support vessels, transfer to the shore base, and onward handling by licensed waste contractors. The Project will not rely on municipal or port-operated waste management services for treatment or disposal. Instead, waste will be transported directly to authorised regional facilities in accordance with the Project Waste Management Plan and applicable national legislation. Waste transfer operations will occur periodically throughout the approximately 67-day drilling campaign, and no new waste treatment, storage or disposal infrastructure will be required. In addition, waste segregation at source will maximise opportunities for recycling and recovery, thereby reducing the volume of waste requiring final disposal.

Hazardous waste received at the shore base will be stored only temporarily in designated containment areas for the minimum time required to organise onward transport, thereby avoiding prolonged storage and limiting any pressure on local infrastructure.

Accordingly, no significant effects on the existing waste management infrastructure of the Port of Igoumenitsa or the wider municipal waste management system are anticipated.

Wastewater generated by the small shore-based workforce (approximately six personnel) will consist primarily of sanitary effluent from portable chemical toilets serviced by licensed contractors and will not place a material demand on municipal wastewater treatment infrastructure. Offshore wastewater generated by the MODU and support vessels will be managed onboard in accordance with MARPOL requirements and either discharged offshore under controlled conditions or transferred where necessary, without reliance on municipal wastewater systems. Overall, the Project is not expected to result in adverse effects on the capacity or operation of existing wastewater infrastructure.

In summary, with regard to their significance, the impacts on environmental infrastructure during the drilling operations phase are assessed as negative (–), of low intensity (IN=2), extending to the regional area (EX=4), immediate (MO=4), temporary throughout the drilling period (PE=1), short-term and fully reversible following cessation of activities (RV=1), with limited synergistic effects with existing port operations (SI=2), direct (EF=4), periodic (PR=2), with short-term recovery after completion of drilling (MC=2), and non-cumulative (AC=1). Overall, these impacts are assessed as **minor**.

| Impacts on environmental infrastructure        |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |     |                            |                     |

### 10.1.12.4.3 Demobilisation and abandonment phase

During the demobilisation and abandonment phase, interactions with environmental infrastructure will be associated with the removal of offshore equipment, the decommissioning of the MODU spread, and the systematic return of materials, consumables and waste streams to the shore base at the Port of Igoumenitsa for onward management. During this phase, waste will predominantly consist of residual municipal waste, packaging materials, scrap metal, surplus consumables, cleaning materials, used absorbents and limited quantities of hazardous waste generated from equipment cleaning, maintenance activities and decommissioning operations.

In addition, accumulated offshore waste retained onboard for controlled disposal onshore—such as oily residues, waste chemicals, contaminated materials and other non-dischargeable waste streams—will be transferred to the shore base and to appropriately licensed waste management facilities via approved contractors under the Project Waste Management System.

Based on indicative estimates, approximately 2.3 tonnes of non-hazardous waste may be managed at the shore base during demobilisation activities, in addition to offshore-generated waste. All waste streams will be handled through the Project's dedicated waste management arrangements and transferred to authorised facilities in accordance with applicable regulatory requirements and the Project Waste Management Plan.

Although demobilisation represents a short-term peak in waste handling and logistics activity, the quantities involved are modest and will be managed through appropriately authorised contractors and facilities selected in accordance with the Project Waste Management Plan. No reliance will be placed on expansion of municipal infrastructure, and no new waste treatment or storage facilities will be required. Utility use at the shore base will progressively decline as offshore assets are demobilised and onshore support activities cease operation. Once demobilisation is complete, all temporary facilities and associated infrastructure will be removed, retained or transferred as agreed with the relevant facility operator, and no residual demand on local environmental infrastructure is expected.

In summary, with regard to their significance, the impacts on environmental infrastructure during the demobilisation / abandonment phase are assessed as negative (-), with negligible intensity (IN = 1), localised (EX = 1), occurring immediately during demobilisation activities (MO = 4), coincident with the demobilisation period (PE = 1), short-term and fully reversible (RV = 1), with moderate synergistic interaction effects (SI = 2), direct (EF = 4), discontinuous in nature (PR = 1), characterised by short-term recovery potential (MC = 2), and non-cumulative (AC = 1). In terms of their overall significance, these impacts are assessed as **negligible**.

| Impacts on environmental infrastructure   |            |                |             |             |                  |                    |              |             |                  |               |                   |                       |                            |

### 10.1.13 Summary of impacts from the regular / routine operation of the project

---

This section summarises the environmental and social impacts arising from the regular (routine) operation of the Project. The summary is based on the detailed assessments presented in the preceding sections and provides the corresponding impact significance and residual significance following the implementation of the proposed mitigation measures.

**Table 10-21: Summary of impacts from the normal/routine operation of the project**

| Environmental & Social Parameters             | Valued Receptors         | Project Activities / Elements                                                                                                   | Nature (S) | Intensity (IN) | Extent (EX) | Moment (MO) | Persistence (PE) | Reversibility (RV) | Synergy (SI) | Effect (EF) | Periodicity (PR) | Recovery (MC) | Accumulation (AC) | Impact Magnitude (Im) |            | Valued Receptor Assessment | Impact Significance | Final Residual Impact Evaluation |

## 10.2 Assessment of impacts deriving from the vulnerability of the project to risks of major accidents and/or disasters

The purpose of this section is to present and document the information required to support the analysis of potential impacts arising from the vulnerability of the Project to risks of major accidents or disasters, as provided for under Article 2 of JMD 5688/12-03-2018 (GG 988/B/21-03-2018), “Amendment of the annexes to Law 4014/2011 (A’ 209), pursuant to Article 36A of that Law, in compliance with Directive 2014/52/EU”, and Article 3(3) of JMD 1915/2018 (GG 304/B/2-2-2018), “Amendment of Joint Ministerial Decision 48963/2012 (B’ 2703), Joint Ministerial Decision 167563/2013 (B’ 964) and Ministerial Decision 170225/2014 (B’ 135), issued under the authorisation of Law 4014/2011 (A’ 209), in compliance with Directive 2014/52/EU amending Directive 2011/92/EU on the assessment of the effects of certain public and private projects on the environment”, of the European Parliament and of the Council of 16 April 2014.

JMD 172058/2016 (GG B’ 354/17.2.2016) establishes rules, measures and conditions for the control of major-accident hazards involving dangerous substances and applies where the relevant scope and dangerous-substance thresholds are met.

The assessment of impacts deriving from the Project’s vulnerability to risks of major accidents and/or disasters has considered major accident and disaster scenarios that could occur during the Asopus-1 offshore drilling campaign and that may result in consequences beyond routine operational impacts. The relevant scenarios, as described in the Project’s QRA (Chapter 9) include blowouts, fires, explosions, toxic releases, marine accidents, loss of position, structural failure, reduction in stability, dropped objects and helicopter-related incidents. These scenarios are low-frequency events, but they are assessed because of their potential to cause significant safety, environmental or transboundary consequences.

### 10.2.1 Environmental and social receptors that may be affected in the event of a major accident or disaster

Table 10-22 identifies the environmental and social receptors that may be affected in the event of a major accident or disaster associated with the Project. This screening is based on the major accident hazards identified for the Asopus-1 drilling campaign (Chapter 9). Accident scenarios are assessed separately from routine operational impacts.

For each scenario, receptors have been screened according to whether a credible impact pathway exists. Such pathways may include accidental releases of hydrocarbons, fuels, chemicals or wastes to sea, atmospheric emissions from fire or explosion events, underwater or airborne noise, waste (debris) generation, seabed pollution/disturbance, disruption to maritime activities and risks to personnel and other marine users.

Several environmental parameters are not expected to experience significant impacts from major accident or disaster scenarios and are therefore scoped out from detailed assessment:

- No material impact on microclimate is expected. Although a fire or explosion could generate short-term heat and smoke near the MODU, these effects would be localised and temporary and would not alter microclimatic conditions.

- No impact on tectonics or seismicity is expected. The Project does not involve hydraulic fracturing, large-volume injection, production, reservoir depletion or underground storage. Seismicity is relevant only as an external natural hazard that could affect well integrity or subsea equipment, rather than as an impact caused by the Project.
- No direct impact on terrestrial habitats, vegetation or terrestrial fauna is expected from offshore accident scenarios. Potential effects would be limited to unlikely onshore accident conditions where contaminants migrate beyond paved or engineered areas, or where an onshore spill, fire or helicopter accident occurs near terrestrial habitats. Where a credible pathway beyond existing operational areas is identified, the potential consequences are considered under the relevant onshore accident scenario; otherwise, these receptors are scoped out.
- Direct effects on marine vegetation and underwater flora are not anticipated, as the offshore well location is in deep water where marine vegetation is not expected. Effects in shallower coastal waters would only be possible under a worst-case spill scenario in which hydrocarbons or pollutants drifted towards coastal habitats.
- No significant impact from electromagnetic radiation is expected. Emergency communications, radar, navigation and monitoring systems may be used during incident response, but these would remain within normal maritime and aviation operating parameters.
- No significant impact on energy or telecommunications infrastructure is expected under major accident scenarios. Potential interaction could occur if emergency response or accident conditions disrupted communications systems, offshore operational monitoring or port and airport coordination, but physical damage to regional energy or telecommunications infrastructure is not anticipated.

The matrix (Table 10-22) therefore provides a structured basis for identifying which receptors require further consideration in the assessment of impacts deriving from the Project's vulnerability to risks of major accidents and/or disasters. It should be noted that inclusion of a receptor in the matrix does not imply that an impact will occur, but only that a plausible pathway exists under the relevant accidental scenario.

Table 10-22: Environmental and social receptors that may be affected in the event of a major accident or disaster

| MAJOR ACCIDENT SCENARIOS                                          | SIGNIFICANT ENVIRONMENTAL PARAMETERS (SEPS) |                |                                               |           |                                               |                 |                          |      |                      |                                   |                                        |                                                   |              |                 |                 |                          |                               |                               |               |                                                          |                   |                       |                          |                       |                         |                                |                                                                |                              |             |                 |                  |            |                           |          |                |             |  |

## 10.2.2 Accident scenarios

### 10.2.2.1 Blowout and well release scenarios

---

A blowout is defined as an uncontrolled release of fluid from a well. The most significant hazard is the uncontrolled release of hydrocarbons to the surface, although drilling mud, wellbore fluids or water may also be released. Blowout risks are important because they have the potential to release large quantities of hydrocarbons, may be difficult to control, and could cause significant damage to the drillship and the environment, as well as posing a major threat to personnel.

The identified blowout scenarios include hydrocarbon blowouts located on the drill floor, in the moonpool, in the mud processing room and subsea, as well as shallow gas blowouts. These scenarios represent the principal major accident events with potential environmental consequences, particularly when a release escalates into fire, explosion, gas dispersion or loss of containment to the marine environment.

Ignited blowouts may result in jet fires, thermal radiation, smoke generation, structural damage and escalation. In the case of a drill floor fire, flames could affect the drill floor and drill tower area, while delayed ignition may result in flash fire or explosion, generating overpressure capable of damaging critical equipment or causing fatalities. Thermal radiation and smoke from an ignited blowout could also impair temporary refuge, lifeboats or other safety functions if the event escalates.

Unignited blowouts may result in gas dispersion. The consequence assessment indicates that gas ingress to temporary refuge could cause asphyxiation or explosion if ignited, although temporary refuge impairment is dependent on gas or smoke dispersion, air intake location, HVAC shutdown and sealing performance. The integrity of the HVAC system is therefore identified as critical to the ability of the temporary refuge to provide its safety function.

For subsea blowouts, hydrocarbon fluids rise to the surface due to their relatively low density, while gas releases rise rapidly and expand as hydrostatic pressure decreases. At the Asopus-1 water depth of approximately 840 m, the QRA consequence modelling does not predict a sustained flammable gas cloud at the topsides under the assessed subsea blowout scenarios. However, a subsea blowout remains an environmentally significant scenario because the release may still result in environmental consequences in the water column or at the sea surface.

### 10.2.2.2 Fire, explosion and toxic release

---

#### 10.2.2.2.1 Fire, explosion and smoke

Fire and explosion scenarios may arise from well-related events, mud treatment areas or other onboard areas.

Drilling fluid required for planned and emergency operations is treated, stored and circulated in the mud system on the MODU. The main mud treatment areas include mud pits, shale shaker room and mud pump room. Potential causes of explosion in these areas include the accumulation of gas in the mud system,

particularly where gas from the well is brought back to the MODU with the returning drilling mud during well-control operations. Explosion risk may also increase if ventilation is insufficient to disperse this gas, allowing flammable concentrations to build up within enclosed or semi-enclosed mud treatment areas.

According to the consequence assessment for fire in mud treatment areas, the probability of escalation to surrounding areas is 0.015, based on the presence of appropriate protection measures. However, none of the reported mud area incidents examined in the QRA were found to escalate beyond the area of initiation. Therefore, based on the QRA screening criteria, the low escalation probability and the credited protection measures, this event was not taken forward for detailed consequence modelling.

Other fire events include fires and explosions not related to well operations. These may involve hydrocarbons such as helifuel, diesel and lube oil, or non-hydrocarbon fires such as accommodation, electrical or chemical fires. Although many such fires are limited in size and duration, some recorded events have caused severe damage and fatalities. The identified examples include fire in accommodation and fire in the main engine rooms.

Accommodation fire scenarios may involve the galley or laundry areas. Fire spread is considered unlikely in these cases because of limited combustible inventory and fire-rated construction, although smoke logging of the accommodation may occur. In an escalated accommodation fire, the integrity of the main control room could be compromised because it is located above the accommodation block.

A fire in the main engine room could involve a potentially large volume of fuel oil. Possible initiating causes include fractured fuel lines, leaks from the fuel system contacting hot surfaces, oily rags close to hot machinery and welding work. The engine rooms are protected by gas, smoke and flame detection, fire alarm pushbuttons, fixed CO<sub>2</sub> extinguishing systems, portable firefighting equipment and fire hose stations.

#### 10.2.2.2.2 Toxic gas release

Toxic gas, particularly H<sub>2</sub>S, may occur naturally in the reservoir or formation being drilled. Significant quantities could be released during a well control situation, when circulating out following a kick, during an actual blowout or through a leak from well test equipment (not planned for Asopus-1). H<sub>2</sub>S may also become entrained in drilling mud and be brought onboard with mud returns.

The assessment identifies H<sub>2</sub>S primarily as a major accident and personnel safety hazard, with potential implications for emergency response and control of the incident. Detection and mitigation measures include H<sub>2</sub>S detectors in areas where gas is most likely to be released, alarm activation at 10 ppm, high toxic gas alarm at 20 ppm, emergency shutdown actions and automatic ventilation control in the affected area. The QRA assumes that where the potential for H<sub>2</sub>S is identified through available well and formation information, additional measures would be implemented in accordance with the approved drilling programme and relevant H<sub>2</sub>S procedures.

### 10.2.2.3 Marine events

#### 10.2.2.3.1 Marine collision

During normal offshore operations, the MODU will be exposed to collision risks from passing merchant vessels, fishing vessels in transit and supply vessels travelling to the drillship location.

Where an errant vessel is heading towards the drillship, radio or other communication would be used to establish contact and determine the vessel's status. If this fails, preventive action may include disconnecting the riser and attempting to move off. If move-off is unsuccessful, collision with the drillship could impact hull tanks containing diesel or base oil. In such a case, the main damage is expected to be environmental and asset-related, with the severity of environmental damage depending on the inventory of oil onboard the drillship.

The QRA identifies two main collision avoidance measures once a threat has been confirmed: warning the threatening vessel through available communication means, and disconnecting and moving the drillship to a safe location. The support vessel, when available, may also be used to avert collision through sound and light signals, although successful avoidance depends on the approaching vessel being manned and capable of corrective action.

#### 10.2.2.3.2 Structural failure and reduction in stability

Structural failure may be influenced or accelerated by structural weakness, design or fabrication defects, incorrect modification, inadequate maintenance, inspection or testing, overloading due to human error or extreme weather, and consequences of fires, explosions, reduction in stability, impact or grounding. Such failure may develop into a major accident through compartment flooding, reduction in stability, loss of structural strength or progressive collapse.

The consequence assessment indicates that structural failures are most likely to result in fatalities where evacuation is required, particularly if the drillship founders or capsizes, or where listing is so severe that capsize appears likely. These events are normally considered to occur in moderate or severe weather, where evacuation is hazardous. Any event resulting in capsize is likely to result in severe environmental damage.

Reduction in stability may be caused by flooding following vessel collision, structural failure or extreme environmental conditions. It may lead to vessel capsizing with potential material and environmental consequences. In rapid foundering or capsize scenarios, there may be insufficient time for evacuation using TEMPSC (Totally Enclosed Motor Propelled Survival Craft), and the chance of rescue and recovery is assessed as low under severe weather conditions.

#### 10.2.2.3.3 Loss of dynamic positioning or loss of position

Loss of position occurs when there is an unintentional move-off of the drillship. This may result from thruster failure, loss of power, malfunctioning computer software or reference system failure. The relevant scenarios include large excursions, drift-off and drive-off. The MODU DP control system is designed to comply with DNV

DYNPOS AUTRO, equivalent to IMO DP Class 3, requiring fully redundant propulsion and control systems so that no single failure can disable both systems.

Large excursions are treated as operational in nature. Drift-off may result from loss of power to the thrusters, while drive-off may result from faults in thrusters, control systems or position reference systems. In a drive-off event, the drillship may move towards an incorrect reference point or accelerate away from the correct position if the DP control system fails to respond appropriately.

Following a loss of position incident, attempts would be made to close the BOP and disconnect the riser. If closure and disconnection are successful, the QRA assumes no significant damage except where the riser hits the seabed. If disconnection is unsuccessful, the QRA models riser parting and BOP closure. The fail-safe system incorporated into the BOP means that, in most cases, the BOP is designed to initiate closure if a loss of position occurs.

Loss of station keeping is not predicted by the QRA to result in loss of life or impairment of safety functions under the assessed base scenarios, and environmental consequences are expected to be negligible. It is also expected to have negligible environmental consequences unless the BOP fails to close or disconnection fails. In that unlikely escalation case, failure to close the BOP could result in environmental damage.

#### 10.2.2.3.4 Dropped object scenarios

Dropped object hazards include dropped objects from main cranes, accommodation service cranes, pipe handling cranes, riser gantry cranes, BOP overhead crane, xmas tree handling crane, SBOP crane and the mast. Dropped loads from cranes, the drill tower or other lifting devices could result in injuries or fatalities, release of hazardous material if the object falls on deck or seabed, or damage to structural support.

The greatest risk from dropped objects is to personnel through direct impact, striking or crushing. Dropped objects may also impact or puncture critical equipment or structural elements, although the probability of such events impairing safety functions or requiring evacuation is considered low because of the limited topsides inventories on the MODU and the assumed application of lifting procedures consistent with industry good practice.

Subsea dropped objects are mainly relevant where they could impact subsea infrastructure. As the MODU will operate in deep water, the likelihood of a dropped object directly impacting equipment below the vessel is considered very unlikely, as the object may be carried by currents and deviate horizontally during descent. Any hydrocarbon release following impact on subsea infrastructure would disperse in the water column, and ignition is considered unlikely.

Dropped objects on the drill floor could cause a well-control problem if critical equipment were damaged, but the likelihood is considered very low given the design and high level of automation of the drillship tubular handling system. The probability of safety function impairment due to dropped objects is expected to be negligible, and dropped objects are not considered to cause environmental damage under the assessed scenarios.

#### 10.2.2.3.5 Helicopter accident

Helicopter-related major accident scenarios include incidents occurring on or close to the MODU, incidents during transit between the shore base and the MODU, and accidents during take-off or landing. The QRA considers both the in-flight stage and the take-off and landing stages, including the potential for a helicopter crash on the installation. For the base case, helicopter flight time is assumed to be approximately one hour in total, comprising 30 minutes each way.

Potential helicopter accident scenarios include:

- Heavy landing or crash onto the helideck, with the possibility of subsequent fire,
- crash into the sea,
- crash onto other areas of the drillship,
- approach or landing accident in which the helicopter continues beyond the helideck and impacts the bridge, control room or other safety-critical structures.

These scenarios are primarily associated with risks to personnel and assets. However, escalation could occur if a crash or subsequent fire affects the helideck, control room, bridge or other safety-critical areas of the MODU.

#### 10.2.2.3.6 Spill to sea, including diesel bunkering or helifuel tank rupture

Accidental spills to sea may occur as a result of diesel release during bunkering operations or rupture of a helifuel tank. The main impact pathway would be the accidental release of fuel to the marine environment, resulting in localised contamination of seawater and, depending on spill volume, weather conditions and response effectiveness, potential exposure of marine fauna, seabirds, fish, plankton and surface-feeding organisms. Diesel and aviation fuel are relatively light petroleum products and may evaporate and disperse more rapidly than heavier oils. However, they can still cause acute toxic effects, surface sheening, localised water quality deterioration and physical exposure of birds or marine fauna if not rapidly contained.

The receptors most likely to be affected are seawater quality, marine fauna, avifauna, marine habitats, fisheries and maritime traffic. Potential indirect effects may also occur on economic activities where a spill causes temporary exclusion from an area, affects fishing activity, or requires emergency response measures. If residues settle or are dispersed through the water column, localised effects on seabed quality and benthic habitats may also occur, although this is expected to be limited for small-volume light fuel releases.

The likelihood and scale of impacts will be reduced through standard bunkering procedures, inspection and maintenance of hoses and transfer equipment, use of drip trays and containment arrangements, supervision of fuel transfer operations, emergency shutdown procedures, weather-related operational restrictions, secure storage of helifuel, spill response equipment onboard the MODU and support vessels, and implementation of the Project's Emergency Response Plan. Any spill would be reported and managed in accordance with applicable marine pollution response and notification requirements.

Overall, spill-to-sea scenarios involving diesel bunkering or helifuel tank rupture could result in short-term, localised adverse impacts on seawater quality and marine ecological receptors. The impact is assessed as negative, direct, temporary and reversible. With the proposed prevention and response measures in place, the residual impact from a small, promptly controlled release is expected to be minor. In the unlikely event

of a larger uncontrolled release or delayed response, impacts could become more significant and may require transboundary notification and coordinated emergency response, in accordance with applicable requirements.

### 10.2.3 Potential impacts deriving from the vulnerability of the project to risks of major accidents and/or disasters

---

The potential impacts addressed in this section are associated with the Project's vulnerability to major accidents and/or disaster scenarios, rather than with normal Project operations. The principal accident-related pathways comprise accidental releases to sea, atmospheric emissions from fire or explosion events, marine pollution, disturbance or harm to marine fauna and seabirds, disruption to maritime activities, temporary pressure on emergency and environmental infrastructure, and risks to offshore personnel and emergency responders. The likelihood and severity of these events will be reduced through well-control barriers, BOP systems, DP Class 3 redundancy, collision avoidance procedures, marine coordination, fire and gas detection, emergency shutdown systems, spill prevention and response arrangements, weather monitoring, emergency preparedness and compliance with applicable offshore safety requirements.

#### 10.2.3.1 Marine pollution and water quality

---

##### 10.2.3.1.1 Seawater – oil spill modeling

Seawater is one of the key receptors in the event of a major accident. A blowout, spill, collision, capsizing, loss of containment, discharge of firefighting water, or release of chemicals or fuels could affect seawater quality. Potential effects may include hydrocarbon contamination, dissolved pollutants, increased turbidity, increased oxygen demand and toxicity to marine organisms. These effects would be most relevant in scenarios involving an uncontrolled well release, vessel collision affecting fuel or chemical inventories, loss of containment, or emergency response activities that generate contaminated waters or residues.

Oil spill modeling was undertaken to support the assessment of potential non-routine impacts on seawater quality in the event of an accidental surface release of Marine Gas Oil (MGO) as presented in Chapter 9.

The modeling was carried out using OSCAR (Oil Spill Contingency and Response), a numerical model developed by SINTEF for simulating the fate of oil at sea. OSCAR can evaluate the evolution of oil on the water surface, in the water column and along shorelines, including oil fate and weathering processes. The model may be applied deterministically, for a specific time-window scenario, or stochastically, through multiple deterministic simulations used to generate probabilistic outputs for oil fate, including affected areas, minimum arrival times and probabilities of oil reaching different parts of the model domain.

##### Input data and assumptions

For the surface spill scenario, an instantaneous release of 2,201 bbl, equivalent to 350 m<sup>3</sup>, was modelled. The simulation duration for the surface spill was 30 days, which was considered sufficient for the main oil weathering processes to occur. The oil type used for the surface release was MGO, represented in the OSCAR database by MGO 500 PPM. The properties used for this oil include a specific gravity of 0.852 g/cm<sup>3</sup>, viscosity of 6 cP at 10 °C, pour point of -36 °C, wax content of 0.81% and asphaltene content of 0.02%.

The modeling considered two seasonal periods: Season 1, from October to March, and Season 2, from April to September. These seasons were selected to represent the main metocean variability in the study area. Season 1 corresponds to the winter circulation regime, characterised by stronger and more variable winds and enhanced cyclonic activity, while Season 2 represents the summer circulation regime, with more stable atmospheric conditions, prevailing northwesterly winds over the Ionian Sea and lower average wind speeds.

The principal environmental inputs to the model comprised wind, current, temperature, salinity, bathymetry and coastline classification data. Temperature and salinity profiles were derived from CMEMS data, with seasonal variations considered. Ocean current fields were obtained from the Copernicus Marine Service Mediterranean Sea Physics Analysis and Forecast product, while wind data were obtained from the ERA5 atmospheric reanalysis produced by ECMWF. At the release point, currents were predominantly towards the west and west-southwest in Season 1 and towards the southwest and west-southwest in Season 2, with most current intensities between 0.1 and 0.2 m/s.

The model grid covered a zonal extent of 2,000 km and a meridional extent of 1,800 km, with a horizontal resolution of 2,000 m. For the surface release scenario, the vertical grid resolution included a 2 m surface layer and 10 m layers below, with a maximum concentration grid depth of 202 m. The model calculation time step was 15 minutes, with model outputs generated every 60 minutes. A total of 500 stochastic simulations were performed for each season.

Bathymetry was based on GEBCO data at 30 arc-second resolution. Shoreline interaction in the model was represented using the GCL\_FCS30 global coastline dataset, which provides coastline classification at 30 m resolution. The coastline types considered in the study area included rocky shore, sandy beach, sheltered artificial structure, tidal flat and mangrove/marsh/vegetated river mouth.

For interpretation of the results, threshold values were adopted for surface oil, water-column concentrations and shoreline oiling. A surface oil threshold of 0.3  $\mu\text{m}$  was used, corresponding to rainbow sheen appearance under the Bonn Agreement Oil Appearance Code. A water-column threshold of 0.058 ppm was applied for dispersed oil, based on guidance for acute oil pollution effects on fish. A shoreline oiling threshold of 1 g/m<sup>2</sup> was used to identify coastal segments affected by stranded oil at levels relevant to recreational restrictions and cleanup activities.

## **Results and Conclusions**

The stochastic simulations for the instantaneous MGO surface spill scenario indicate that the highest-probability effects are concentrated near the release location, while lower-probability transport may extend over substantially greater distances, mainly due to the light refined nature of MGO, the instantaneous release and the rapid weathering and evaporation of the product. Surface oil drift was predicted in all directions from the release location in both seasons; however, the highest probabilities of occurrence were concentrated close to the release point and predominantly to the southwest, influenced by prevailing northerly winds and westward to northwestward surface currents.

At the sea surface, the maximum extent of oil drift for probabilities greater than 90% was approximately 2 km from the spill location in both seasons. For probabilities greater than 30%, the maximum distance reached was approximately 4 km in Season 1 and 8 km in Season 2. Low-probability oiling could extend farther, reaching up to 122 km in Season 1 and 166 km in Season 2.

Within the water column, oil occurrence was mainly limited to the upper layers. Concentrations above the 0.058 ppm threshold were predicted from the surface to approximately 60 m depth in Season 1 ( ) and 45 m in Season 2 (Figure 10-4), with maximum concentrations of 1.19 ppm and 1.041 ppm respectively, occurring at approximately 10–20 m depth.

Figure 10-3: Maximum water column oil concentration and latitudinal vertical profile (> 0.058 ppm) for Surface MGO Spill, Season 1

GREECE | Block P2 | MGO  
Surface Oil Spill | Season 2  
Maximum Oil Concentration in Water Column (>0.058 ppm)

**Figure 10-4: Maximum water column oil concentration and latitudinal vertical profile (> 0.058 ppm) for Surface MGO Spill, Season 2**

Shoreline oiling was predicted as possible but with low probabilities. In Season 1, shoreline oiling may occur in five countries between Croatia and Greece, while in Season 2 it may occur in four countries. The highest shoreline oiling probability was predicted for Italy, reaching up to 5% in Season 1 and 12.2% in Season 2. The shortest shoreline arrival times were 2.8 days in Italy during Season 1 and 2.2 days in Greece during Season 2. These results are conservative, as they assume that no oil-spill response or mitigation measures are implemented.

The stochastic mass balance shows that dispersion within the water column and evaporation are the dominant fate processes. After 30 days, less than 0.05% of the released oil remained at the sea surface in both seasons, confirming the limited persistence of MGO at the sea surface.

Overall, the MGO surface spill scenario indicates a short-term and comparatively limited impact on seawater quality. The main effects would be temporary surface oiling near the release location, short-term dispersion in the upper water column and limited potential shoreline contact. Rapid evaporation, dispersion and biodegradation would substantially reduce surface oil persistence; therefore, the impact is assessed as temporary and mainly localised to regional depending on metocean conditions.

#### 10.2.3.1.2 Surface water and groundwater

Offshore accident scenarios would not directly affect inland surface waters. However, a potential pathway exists at onshore support areas if fuels, oils, chemicals, firefighting water or contaminated runoff entered the port stormwater drainage system or nearby coastal waters. Such effects would be localised and would depend on the scale of the release, the affected area, and the effectiveness of containment and response measures.

According to the oil spill modeling (Section 10.2.3.1.1), in both deterministic scenarios oil initially drifted northeastward and reached Othoni Island in Greece after approximately 2.25 days in the Minimum Arrival Time scenario and 2.79 days in the Maximum Mass on Shore scenario. No oil concentrations above the 0.3  $\mu\text{m}$  surface threshold were detected after approximately 10 days.

Predicted shoreline concentrations varied between the assessed deterministic scenarios. In the Minimum Arrival Time scenario, oil reached Othoni Island with an initial concentration of approximately 0.001  $\text{kg}/\text{m}^2$ , increasing to 0.193  $\text{kg}/\text{m}^2$  by the end of the simulation. In the Maximum Mass on Shore scenario, the final coastal accumulation reached 2.67  $\text{kg}/\text{m}^2$ . Shoreline oiling represented approximately 0.4% and 5.2% of the released mass in the two deterministic scenarios, while sedimentation remained negligible.

Groundwater impacts are not expected from offshore scenarios. At onshore support areas, a groundwater pathway could arise only if spills or contaminated firefighting water infiltrated through damaged paved surfaces, cracks, drainage points or unsealed areas. With containment and spill response measures, significant groundwater impacts are expected to remain unlikely.

#### 10.2.3.2 Seabed, morphology, marine geology and slope stability

Accident-related impacts on the seabed could arise from a subsea blowout, dropped objects, riser or BOP damage, sunken debris, vessel loss, or the release of hydrocarbons, drilling fluids or chemicals. Potential effects may include local physical disturbance, smothering, contamination or debris deposition. These effects would be associated with the immediate affected area and are not expected to result in a regional seabed impact.

Potential impacts on seabed morphology would be limited to exceptional scenarios such as a subsea blowout, dropped object, riser or BOP damage, structural failure, or sinking of equipment. Effects could include local sediment displacement, debris deposition, crater formation or localised disturbance of seabed features. Regional seabed morphology is not expected to be affected under the assessed scenarios.

Impacts on geology and marine geology could occur in the event of blowout, loss of well control or failure of well barriers. Such effects would be confined to the wellbore, surrounding formations and immediate subsurface environment. No regional geological or marine geological change is expected.

Potential effects on slope stability would be limited to highly localised disturbance from subsea release, dropped objects, riser contact or debris. Earthquakes or extreme weather may act as external hazards affecting the MODU, wellhead or BOP systems; however, no mechanism is expected through which the Project would trigger regional slope instability.

### 10.2.3.3 Air quality

---

Air quality could be temporarily affected in the event of fire, explosion, smoke dispersion, gas release or combustion of hydrocarbons and fuels. The main pathway would be short-term deterioration of local air quality around the MODU or accident location. Smoke and gas dispersion from ignited and unignited blowouts have been considered in the consequence assessment. Due to the offshore location of the drilling campaign, significant onshore air-quality effects are unlikely, except under extreme accident scenarios.

A major fire, explosion or uncontrolled hydrocarbon release could also generate greenhouse gas emissions through combustion, emergency response and spill recovery activities. These emissions would be accidental and short-term. They would not represent a routine Project emission source and are not expected to materially affect climate-change trends or national climate targets.

### 10.2.3.4 Noise and vibration

---

Airborne noise may increase temporarily during an accident or emergency response. Potential sources include explosions, alarms, emergency response vessels, helicopters, firefighting and evacuation activities. These effects would be short-term and would occur mainly offshore or within existing operational port or airport areas. Vibration effects may also arise locally from explosion, collision, structural failure, dropped objects or emergency operations, but would be short-term and localised, with no expected measurable effect on coastal receptors.

Underwater noise could increase during emergency response, vessel manoeuvring, ROV intervention, well-control operations, debris recovery or spill response. Explosions, collision or structural failure could also generate short-duration underwater acoustic events. Effects on marine fauna would depend on proximity, duration and intensity of the noise source.

### 10.2.3.5 Marine biodiversity, avifauna and protected areas

---

Marine fauna is a key receptor in major accident scenarios. Potential impacts may include exposure to hydrocarbons, dissolved contaminants or toxic substances, underwater noise from emergency operations, physical injury from debris, and disturbance from response vessels or aircraft. A major subsea release or surface spill could affect fish, marine mammals, sea turtles and planktonic communities.

Avifauna may be affected in the event of a surface hydrocarbon spill, fire, smoke plume, debris field or emergency response activity. Potential impacts include oiling, ingestion of contaminants, displacement from

feeding areas and collision risk associated with emergency lighting or aircraft. These effects would be most relevant for seabirds using offshore waters or areas affected by a surface spill.

The Project footprint does not directly overlap with protected areas. Potential impacts on protected areas could occur only if a major spill or pollutant plume moved beyond the immediate Project area and reached designated marine or coastal areas. Such effects would depend on release volume, release duration, metocean conditions and the effectiveness of emergency response.

#### 10.2.3.6 Soil

---

Offshore major accident scenarios would not affect soil. Potential soil impacts could arise only at onshore support locations, such as the shore base or airport hangar, from accidental releases of fuels, oils, chemicals, firefighting water or contaminated materials during emergency response, storage, transport or waste handling. Such effects would be localised and managed through appropriate containment and spill response.

#### 10.2.3.7 Spatial planning, maritime use and anthropogenic environment

---

No permanent land-use change is expected as a result of major accident or disaster scenarios. However, a major accident could temporarily restrict use of marine space through exclusion zones, emergency response areas, vessel routing controls or temporary occupation of port areas. These effects would be temporary and linked to emergency management.

Potential impacts on the structure and functions of the anthropogenic environment include temporary disruption to port logistics, offshore operations, emergency services, maritime activities and local support functions. A major event may require mobilisation of emergency response resources and temporary restrictions on sea or port use.

Maritime transport and traffic are key receptors. Collision, loss of position, emergency response operations, spill response zones or temporary exclusion areas could disrupt vessel movements. These impacts would be temporary or longer-lasting depending on the nature and scale of the event, and could affect commercial shipping, fishing vessels and support traffic in the wider area.

Other transport infrastructure may be affected through helicopter operations and associated support activities, as well as increased road transport for emergency response, evacuation or waste transfer. These effects would be short-term and operational, with no expected physical impact on transport infrastructure.

#### 10.2.3.8 Economic activities

---

The economic activities most relevant to major accident scenarios are fisheries, maritime transport, port services and tourism. A major spill, collision, blowout or extended emergency response could temporarily restrict fishing grounds, affect navigation, interrupt logistics or create reputational effects for coastal tourism.

### 10.2.3.9 Community health and safety

---

Community health and safety effects are expected to be limited due to the offshore location of the principal accident scenarios. The primary risks would affect offshore personnel and emergency responders. Community health and safety impacts could arise only from an onshore support-base accident, helicopter accident near land, smoke exposure in port areas, or public concern during a major incident.

### 10.2.3.10 Environmental infrastructure

---

Environmental infrastructure may experience increased temporary demand in the event of a major accident. Relevant resources include spill response equipment, waste reception facilities, hazardous waste contractors, firefighting systems, wastewater handling and emergency response infrastructure. The most important pathway is the generation of contaminated wastes, oily residues, firefighting water, debris or damaged equipment requiring licensed management.

### 10.2.3.11 Cultural heritage

---

Potential impacts on cultural heritage are unlikely but cannot be fully excluded under major accident conditions. Subsea dropped objects, debris, anchoring by emergency vessels or a major spill response operation could theoretically affect underwater cultural heritage if present within the affected area. Where consistent with protection of life and emergency-response priorities, known cultural heritage locations will be considered during response planning and operations.

### 10.2.3.12 Landscape

---

Landscape impacts would be limited. Offshore accident scenarios would have limited visual relevance due to the offshore location. A major fire or smoke plume could create a temporary visual effect at sea, while dismantling or emergency operations at the shore base could temporarily affect the industrial port landscape. No permanent landscape impact is expected.

### 10.2.3.13 Summary of potential impacts

---

The most relevant impacts deriving from the Project's vulnerability to major accidents and/or disasters relate to accidental releases to sea, temporary deterioration of seawater and air quality, local seabed disturbance, effects on marine fauna and seabirds, disruption to maritime activities, temporary pressure on emergency and environmental infrastructure, and potential socio-economic effects on fisheries, maritime transport, port services and tourism perception.

The highest-consequence environmental pathways are associated with uncontrolled well release or blowout, major spill, collision, capsized and loss of containment. These events could generate contaminated wastes, disturb marine receptors or require temporary restrictions over marine space.

## 10.3 Assessment of cumulative/synergistic effects

This section assesses the likelihood that the impacts of the Project will interact with or be added to the impacts of other existing, approved or planned permitted and/or planned projects and/or activities in the wider northern Ionian Sea and adjacent coastal areas. The assessment focuses on activities that may overlap with the Project spatially and/or temporally, or that may affect the same environmental and social receptors, namely marine water quality, seabed habitats, marine fauna, fisheries, shipping, air quality, underwater noise, technical infrastructure and existing marine uses.

The assessment takes into account the current framework for maritime spatial planning, existing maritime uses and anticipated offshore activities in the wider study area. The project area is located within Spatial Unit 4 of the National Spatial Strategy for the Maritime Space (NSSMS); given that the detailed Maritime Spatial Planning Frameworks for this unit have not yet been finalised, the cumulative assessment was also based on existing national, regional and sectoral spatial planning instruments relating to shipping, fisheries, aquaculture, tourism, offshore infrastructure, renewable energy sources (RES) and, in particular, offshore wind farms currently at the licensing and development stage within the Italian EEZ, as well as development areas on the Greek side that are at the programme approval stage, and the development of the energy sector.

### 10.3.1 Commercial shipping, ferry services and international shipping

Commercial shipping and maritime traffic are among the main existing maritime uses with the potential to interact with the Project during its implementation period. The Ionian Sea is an important maritime corridor linking the Adriatic Sea, the central Mediterranean, the Suez Canal route and the wider Black Sea region, whilst existing traffic includes cargo ships, tankers, international passenger ferries, cruise ships and other commercial traffic, particularly along the routes linking the Italian ports on the Adriatic with Igoumenitsa, Patras and other Greek ports. Furthermore, in the context of the most recent geopolitical developments in the Persian Gulf and the Middle East (military operations in the south-eastern Mediterranean and the Persian Gulf), the Adriatic Sea is also used by warships. The maritime area west of Corfu, including the wider area of Section 2, falls within a zone of moderate to high shipping traffic, although the regional shipping lanes with the highest density are concentrated further west of Corfu and follow a broader north-west to south-east direction.

Figure 10-5: Average shipping traffic density (all vessel types), 2017–2024, in the Ionian Sea and the wider project area

The Project may interact cumulatively with these activities through the establishment of the 500 m safety zone, the temporary presence of the floating drilling unit and the movements of support vessels between the Port of Igoumenitsa and the location of the exploratory well

‘Asopos-1’. These interactions may require temporary notification of passing vessels regarding their route and could marginally increase local maritime traffic during mobilisation, drilling support and demobilisation (de-mobilisation). However, given the short-term and spatially limited nature of the Project, as well as the maritime safety measures to be implemented – including Notices to Mariners, NAVTEX messages, vessel coordination procedures and standard maritime safety practices – the cumulative impacts on commercial shipping and ferry services are expected to be minor, temporary and reversible.

Potential synergistic effects may arise when the movements of the Project’s vessels coincide with existing traffic of cargo ships, tankers or cruise ships, particularly in adverse weather conditions or when visibility is reduced. These impacts, however, are operational rather than environmental in nature and will be addressed through maritime coordination and navigation safety procedures. Consequently, no significant cumulative impact on international shipping is anticipated.

### 10.3.2 Commercial fishing and fishing grounds

Cumulative impacts on fisheries may arise when pressures associated with the Project are added to existing pressures from commercial fishing vessels operating in or transiting through the wider western Ionian Sea region. The main pressures common to both activities are underwater noise, the presence of vessels, artificial lighting, atmospheric emissions, minor discharges and local disturbance to marine fauna and seabed conditions.

Figure 10-6: GFCM restricted fishing areas in the wider project area<sup>63</sup>

During the drilling campaign, the floating drilling rig and support vessels may temporarily increase overall vessel activity and underwater noise levels in the area surrounding the 'Asopos-1' exploration well site. Where this coincides with fishing vessel activity, it may cause short-term cumulative disturbance to marine fauna, mainly due to vessel noise, manoeuvres, lighting and human activity. Fishing activities may also cause local disturbance to the seabed or resuspension of sediments, which could exacerbate the local impacts of discharges associated with the Project's exploratory drilling and interaction with the seabed.

Synergistic effects are considered likely to occur when fishing activities and Project operations take place simultaneously and affect the same receptors, primarily marine fauna and the complexity of navigation, as the combined presence of fishing vessels, support vessels and the safety zone around the floating drilling unit could temporarily increase disturbance or operational pressure in the immediate offshore area. However, such impacts would be highly localised and short-term. Given that the bulk of fishing activity in the wider western Ionian Sea is concentrated mainly in coastal waters, whilst the Project's footprint is limited to a temporary offshore area of operations, the cumulative and synergistic impacts on fisheries are expected to be negligible to minor, temporary and reversible.

<sup>63</sup> <https://www.fao.org/gfcm/data/maps/fras/en/> (edited by: LDK)

### 10.3.3 Maritime tourism, recreational boating and cruises

Maritime tourism and recreational boating, including the hire of recreational craft and sailing, coastal cruises, recreational boating and cruising, are well established throughout the wider Ionian Sea, concentrated mainly around Corfu, Paxos, Antipaxos, the Diapontia Islands and the coast of Epirus (Error! Reference source not found. ). The main recreational boating routes are in coastal and inter-island waters, whilst the 'Asopos-1' exploratory well is located in offshore waters some distance from the main areas of concentration and movement.

**Figure 10-7:** Density of sailing, recreational and high-speed vessels (Annual average 2017–2024)<sup>64</sup>

A potential cumulative interaction could arise in cases where pleasure craft or cruise ships undertake longer offshore voyages between Greece and Italy and pass through the wider Project area; such interactions would be limited to temporary awareness of vessel movements and avoidance of the 500-metre safety zone. The Project is not expected to affect the main recreational sailing routes, coastal cruise areas, approaches to cruise ports or tourist destinations.

Potential synergistic effects could arise if shipping traffic associated with the Project coincides with the peak tourist season, when the density of recreational craft is highest throughout the Ionian region. However, given that recreational activity is mainly concentrated in the coastal zone, whilst the Project is located offshore, these impacts are expected to be limited. No significant cumulative or synergistic impacts on marine tourism, recreational activities or cruises are anticipated.

### 10.3.4 Aquaculture activities

<sup>64</sup> <https://EMODnet.ec.europa.eu/geoviewer/>

Aquaculture is an established but spatially limited marine use within the wider study area. Marine fish farming takes place along the north-eastern coast of Corfu and the coastline of Thesprotia, including designated or planned aquaculture development areas. These activities are concentrated in protected coastal waters and are spatially distinct from the open waters of Section 2 and the proposed location of the 'Asopos-1' borehole. There are no aquaculture facilities, nor are any planned, within the Project's onshore support area at the Port of Igoumenitsa. The distribution of aquaculture facilities within the wider study area is shown in the Figure below.

Figure 10-8: Distribution of aquaculture facilities in the wider study area <sup>65</sup>

Potential cumulative impacts could include changes in seawater quality, interactions with vessel traffic or incidents of accidental pollution. However, routine discharges from the boreholes will take place offshore and are expected to be rapidly diluted and dispersed, whilst the Project's support activities rely on existing maritime access routes and existing port facilities. Given that the location of the exploratory well is a considerable distance from existing aquaculture areas, with no direct spatial overlap, no significant cumulative impact is expected.

Potential synergistic impacts on aquaculture would only be possible in the event of a major accidental spill capable of reaching coastal waters, provided that no mitigation measures are taken. Such scenarios do not fall within the scope of normal operations and are addressed separately through emergency preparedness,

<sup>65</sup> <https://EMODnet.ec.europa.eu/geoviewer/>

oil spill contingency planning and the assessment of accidental events. Under normal operating conditions, no significant cumulative or synergistic effects on aquaculture are expected.

### 10.3.5 Submarine telecommunications and power cables

---

Submarine cables constitute a permanent technical infrastructure of strategic importance in the Ionian Sea. Various international telecommunications cable systems connect Greece, Italy and other Mediterranean countries, whilst submarine electricity infrastructure also exists in the wider region, concentrated along corridors crossing the central and southern Ionian basin between the coasts of Italy and Greece. The spatial analysis carried out for the Project has identified three cable systems within the study area that are directly relevant to the Project:

- Eagle (under planning), a new trans-Mediterranean cable system connecting Egypt, Albania and Italy;
- Jonah (in operation since 2012), which connects Israel and Italy via the Eastern Mediterranean and the Ionian Sea;
- Asia Africa Europe-1 (AAE-1) (in operation since 2017), a major international telecommunications cable system linking Asia, Africa and Europe, with landing points including Bari (Italy).

Their location in relation to the 'Asopos-1A' exploratory well is shown in the Figure below.

Figure 10-9: Subsea cables in relation to the project area: (a) Eagle, Jonah,<sup>66</sup> and (b) OTEGlobe Kokkini-Bari subsea cable systems

The location of the 'Asopos-1' exploratory well is at least 2,692 m from the cables identified within the study area, the nearest being the AAE-1 cable on the south-western side of the area investigated. The assessment took into account the potential for interaction with this infrastructure, particularly with regard to seabed disturbance, the location of the floating drilling unit, the operations of support vessels and emergency response activities.

The Project does not involve anchoring, trenching, the installation of pipelines or permanent subsea infrastructure. The floating drilling unit will operate using dynamic positioning, and the drilling area is limited to the well site and the immediate operational area. The cable routes will be verified against official nautical charts prior to works and, where required, against information provided by cable operators. Provided that

<sup>66</sup> <https://www.submarinecablemap.com>

standard avoidance and notification procedures are followed, no cumulative impact on subsea cable infrastructure is anticipated.

Potential synergistic effects may arise if the activities of the Project's support vessels, other marine works or emergency operations coincide near the cable corridors. However, given that no seabed intervention is planned along the cable routes and no cable route is expected to cross the operational area, such impacts are considered unlikely and insignificant.

### 10.3.6 Offshore oil and gas installations

The available mapped data on existing offshore oil and gas installations in the wider region indicate that the nearest identified installations are located at a distance of approximately 150 km or more from the proposed location of the 'Asopos-1', concentrated mainly along the Italian coast and in more remote parts of the Adriatic and the central Mediterranean. No comparable operational offshore oil and gas installations have been identified in the immediate vicinity of the area where the exploratory well 'Asopos-1'

Figure 10-10: Offshore oil and gas installations (source: EMODnet)

Potential cumulative interactions with other offshore oil and gas exploration and/or production activities may include atmospheric emissions, underwater noise, vessel traffic, discharges at sea and interactions during emergency response operations. In practice, these routes are not expected to result in significant cumulative impacts, given the considerable distance separating the nearest identified installations from the location of the 'Asopos-1' exploration well. The work involved in the 'Asopos-1' exploration well will be of short duration and will be limited exclusively to exploration, without production testing, gas flaring, permanent installations, subsea production infrastructure, etc. Any overlap in terms of emissions, underwater noise, vessel activity

or marine discharges with existing offshore oil and gas activities is therefore expected to be very limited, temporary and insignificant.

Similarly, it is considered unlikely that any potential synergistic effects will arise, as operational pressures from existing offshore oil and gas installations are not expected to overlap spatially with the area where the exploratory drilling operations for 'Asopos-1' in such a way as to affect the same receptors simultaneously. Consequently, no significant cumulative or synergistic impact is anticipated in relation to existing offshore oil and gas activities.

### 10.3.7 Offshore wind energy, ocean energy and other offshore renewable energy sources

Renewable energy projects in the open sea, in particular offshore wind energy, are considered to be reasonably foreseeable activities in the wider Ionian Sea and the Greek maritime area. Greece has established a specific regulatory framework for the development of offshore wind farms under Law 4964/2022, under which EDEYEP has been designated as the authority responsible for the planning and management of the development programme, as well as for the designation of Organised Development Areas for Offshore Wind Farms (POAYAP). The draft National Programme for the Development of Offshore Wind Farms (EP-YAP), which was drawn up by EDEYEP and is accompanied by a Strategic Environmental Assessment (SEA, LDK, 2023), identifies a series of initially assessed POAYAPs for medium- and long-term development. In the Ionian Sea, this includes the Diapontia Islands area, which is among the potential areas identified for medium-term development in the draft programme. It should be noted, however, that although the public consultation process for this EIA has been completed and the relevant recommendations regarding environmental conditions have been issued, the relevant Joint Ministerial Decision (JMD) for approval is still pending, which means that the POAYAPs are not certain to be among the final options when and if it is issued.

This Special Area of Conservation is situated north-west of Corfu and is relevant to the Project, given its proximity to the location of the 'Asopos-1' and its potential interaction with existing maritime uses in the wider region of Corfu and the northern Ionian Sea. The area was identified in the EP-YAP plan as a potential site for the development of offshore wind farms; however, as mentioned above, it is not an operational or licensed offshore wind farm.

At the time of the assessment, the NDP-OWF had not yet been formally approved, and the subsequent stages required to define specific OWFODAs, allocate development capacity, select developers through a competitive process and obtain project authorisation had not been completed.

Consequently, and overall, there is no sufficiently defined or approved offshore wind energy project in the area of the 'Asopos-1', for which it could reasonably be expected that its construction or operation would overlap with the approximately 90-day exploratory drilling campaign.

The offshore wind farm in the Diapontia Islands remains at the planning stage – initially involving the selection of a broader development area – and the exact boundaries, its design, licensing, contractor and construction programme have not yet been finalised; consequently, the likelihood of temporal and spatial overlap with the Project is currently considered to be zero.

The possibility of cumulative impacts from offshore wind energy projects in adjacent Italian waters has also been examined; such impacts would mainly concern navigation, vessel traffic, fishing, underwater noise and the coordination of emergency response. Given the geographical distance from the Project and the absence of any identified construction or operational activities expected to overlap with the Project period, no significant cumulative or synergistic impacts are anticipated. Most other mapped offshore wind farm and ocean energy projects are located considerably further away, mainly along the Italian coastline and elsewhere in the central Mediterranean.

**Figure 10-11: Offshore wind farms and marine energy projects (Source: EMODnet)**

As no existing or even under-construction offshore wind farm or marine energy project has been identified in the immediate vicinity of the Project, no current cumulative interaction is expected. Should offshore renewable energy projects proceed in the wider area in the future, potential cumulative impacts may arise in relation to vessel traffic, seabed disturbance, underwater noise, the displacement of fishing activities, maritime spatial planning, the coordination of emergency response, and visual or navigational aspects.

Potential cumulative impacts could arise in the future if construction activities for offshore renewable energy sources – such as seabed preparation, cable laying or wind turbine foundation works – were carried out simultaneously with exploratory drilling or other offshore activities, with potential impacts on marine fauna, fisheries and shipping. However, based on the current status of the mapped projects and the short duration of the work involved in the ‘Asopos-1’ exploratory drilling ‘Asopos-1’, no significant cumulative or synergistic impacts are anticipated at this stage in relation to offshore renewable energy projects.

### 10.3.8 Port activities in Igoumenitsa and land-based support base

The Port of Igoumenitsa is an established international passenger and commercial port. The Project will utilise the existing port infrastructure as a temporary land-based base for mobilisation, resupply, waste disposal, equipment storage, administrative functions and demobilisation – activities which will take place within an existing operational port environment where similar transport, storage, cargo handling and logistics activities are routinely carried out.

The Project will not require any new permanent port infrastructure, port expansion, dredging, land reclamation or upgrades/works to utility networks. Waste will be managed through the Project's Waste Management Plan and by suitably licensed contractors, and not through municipal waste collection or treatment systems. Consequently, the cumulative impacts on port traffic, port infrastructure, cargo handling, vehicle movements, energy and telecommunications networks, as well as environmental infrastructure (including waste transport), are expected to be negligible to minor and temporary.

Potential synergistic impacts may arise when the Project's supply chain coincides with peak periods in ferry operations, commercial freight movements, tourism-related port traffic or other temporary port activities. These interactions will mainly concern operational coordination, traffic management and temporary congestion, rather than long-term environmental impacts, whilst no significant synergistic effect is expected from the port's usual management and planning procedures.

### 10.3.9 Military exercise areas and restricted-access maritime zones

Military exercise areas and temporary restricted-access maritime zones are relevant to offshore activities, as they may impose temporary restrictions on navigation or offshore activities. According to information provided by the Hellenic Navy Hydrographic Service, there are no permanently designated exercise areas, nor are there any temporary restricted-access or exclusion zones currently in force via NAVTEX broadcasts and/or Notices to Mariners (NtMs) within the boundaries of Section 2.

Consequently, no cumulative interaction between the Project and the military exercise areas is currently anticipated. Should temporary military restrictions be imposed during the drilling operations, any potential interactions will be addressed through standard maritime coordination procedures and operational planning. No significant cumulative or synergistic effects are anticipated under current conditions.

### 10.3.10 Combined synergistic effects on shared receptors

In addition to the cumulative impacts specifically related to the activity, the assessment examined whether multiple pressures could be exerted simultaneously on the same receptor.

#### Marine fauna

Potential synergistic factors include the combined effect of underwater noise from the floating drilling unit, the dynamic positioning system, support vessels and existing commercial shipping, combined with the presence of vessels, lighting and temporary disturbance. These pressures may lead to temporary avoidance behaviour by sensitive marine species, particularly marine mammals and sea turtles. However, given the absence of noise from pile driving or long-term construction noise, the temporary nature of the drilling campaign and the offshore location of the well, the likelihood of significant cumulative effects is limited.

### Air quality and climate change

Potential cumulative effects relate to the combined emissions from the floating drilling rig, support vessels, helicopters, port activities and existing regional shipping, which collectively contribute to regional air pollutant loads and global greenhouse gas emissions. However, the project's emissions are temporary, occur offshore and are dispersed under open-sea weather conditions.

### Users of maritime transport

Potential synergistic effects may arise where the temporary safety zone, the movements of project vessels, commercial shipping, fishing activities and recreational boating occur simultaneously. These impacts will be managed through maritime notifications, coordination with the relevant authorities and standard vessel traffic procedures. Given that the safety zone will be of limited size and the operational period short, the combined impacts on access and navigation are expected to be minor.

Overall, the Project is likely to interact cumulatively with existing shipping, fishing, offshore routes, port logistics, subsea infrastructure and foreseeable offshore energy developments, with potential synergistic effects relating primarily to underwater noise, vessel traffic, atmospheric emissions and the temporary displacement of fishing activities. However, given the temporary nature of the exploratory drilling campaign, the absence of permanent offshore infrastructure, the limited spatial footprint, the use of existing logistics infrastructure and the implementation of mitigation and management measures, the Project is not expected to cause significant cumulative or synergistic impacts. The remaining cumulative and synergistic impacts are assessed as negligible to minor, local, temporary and reversible.

## 10.4 Assessment of transboundary environmental impacts

In accordance with the Espoo Convention, the UNECE Practical Guide on the Implementation of the Espoo Convention and the EU Directive on Environmental Impact Assessment (Directive 2011/92/EU, as amended by Directive 2014/52/EU), the assessment adopted a precautionary approach when evaluating potential transboundary impacts. Should the competent authority consider that the Project is likely to cause significant adverse transboundary impacts, or should a potentially affected Party request to participate, the procedures for formal notification, exchange of information, consultation and public participation provided for in the Espoo Convention shall apply before any final decision on the Project is taken. This will ensure that all potentially affected Parties have an adequate opportunity to examine the environmental information, submit comments and participate in the decision-making process.

### 10.4.1 Geographical boundaries of the area of operation

The 'Asopos-1' exploration well is located within Area 2 of the Greek Exclusive Economic Zone (EEZ) in the northern Ionian Sea, under Greek jurisdiction. The Project comprises both offshore and onshore components, including offshore drilling operations carried out by the Floating Drilling Unit, maritime logistics between the drilling site and the Port of Igoumenitsa, helicopter transfers between Corfu International Airport and the floating drilling unit, as well as the temporary logistics support facilities that have been set up within the Port of Igoumenitsa.

The offshore operations area is situated in the immediate vicinity of the internationally agreed maritime boundary between Greece and Italy. The drilling site is situated approximately 3.16 km (1.71 nautical miles) east of the boundary of the Greece–Italy Exclusive Economic Zone (EEZ), which makes Italy the nearest potentially affected party under the Espoo Convention.

The nearest Italian coastline is Punta Ristola (Santa Maria di Leuca) in the region of Apulia, which is situated approximately 54.9 km (29.7 nautical miles) west of the proposed drilling location. The nearest Greek mainland is the western coast of the island of Othoni, approximately 44.3 km (23.9 nautical miles) from the drilling site. Logistical support for the offshore operations will be provided from the port of Igoumenitsa, which is situated approximately 129.4 km from the drilling site by sea, whilst helicopter transfers will take place between Corfu International Airport and the mobile drilling unit (MODU), a distance of approximately 81.9 km as the crow flies.

The geographical scope of the transboundary assessment extends beyond the immediate footprint of the Project and takes into account the wider marine environment of the northern Ionian Sea, including the adjacent Italian EEZ. Marine currents, atmospheric dispersion, vessel movements and accidents are not confined by administrative boundaries. Consequently, the assessment examines both the direct and indirect pathways through which the Project's activities could potentially affect environmental receptors located within Italian jurisdiction.

Given the relatively short distance from the international maritime border, transboundary aspects have been integrated throughout the EIA, adopting a precautionary and conservative approach, despite the expectation that the Project's normal activities will remain at a highly local level.

A statutory safety zone of 500 m will be established around the floating drilling unit throughout the duration of drilling operations and the decommissioning of the well, in accordance with the United Nations Convention on the Law of the Sea (UNCLOS), applicable Greek legislation and internationally accepted safety practices on the high seas. The safety zone will be centred on the drilling rig and will remain entirely within Greek jurisdiction. Access to the exclusion zone will be restricted to authorised Project vessels and personnel engaged in drilling operations, logistical support, emergency response or regulatory inspections.

Prior to the commencement of operations, the relevant authorities will issue appropriate Notices to Mariners, navigation warnings and updates to hydrographic publications, in order to inform merchant vessels, fishing vessels and other maritime users regarding the temporary exclusion zone. The vessel traffic management procedures to be implemented as part of the Project will ensure safe interaction with existing shipping routes and minimise disruption to international shipping.

The safety zone will cover only a small area compared with the surrounding marine environment and will apply only for the duration of the drilling and abandonment works. Consequently, no significant restrictions on international shipping or fishing activities within Italian waters are expected.

## 10.4.2 Expected transboundary environmental impacts

The assessment systematically examined all possible pathways through which the Project's activities could cause transboundary environmental impacts, taking into account the location of the Exploration Well at a distance of approximately 3.16 km from the boundaries of the Greek-Italy, the temporary nature of the drilling campaign, the characteristics of the host environment, and the natural processes governing the transport

and dispersion of pollutants in the marine and atmospheric environments. The assessment also took into account the nature, magnitude, spatial extent, duration and reversibility of the potential impacts, as well as the built-in mitigation measures included in the Project's design.

The environmental impacts associated with the Project are primarily short-term and temporary, reflecting the exploratory nature of the activity. The impacts are limited to the duration of mobilisation, drilling, well abandonment and demobilisation, and include temporary underwater noise, gas emissions during operations, vessel traffic, limited disturbance to the seabed, routine marine discharges and temporary occupation of the drilling site. These impacts will cease once drilling operations have been completed and the floating drilling unit has been removed.

#### 10.4.2.1 Seawater quality

---

Routine discharges include drilling fluids – water-based muds and drilling cuttings, cooling water, desalination brine, ballast water, sanitary effluent, food waste and other permitted operational discharges managed in accordance with applicable international and national requirements.

The assessment took into account the physical and chemical characteristics of these discharges, as well as the prevailing hydrodynamic conditions, dilution and dispersion processes. These materials are discharged in accordance with the applicable regulatory requirements and undergo rapid dilution and dispersion within the receiving marine environment.

Numerical modelling of drilling discharges into the water column / seawater predicts a relatively extensive but temporary dispersion area which, in some cases, may exceed the distance between the drilling site and the Italian EEZ, as mentioned previously in the relevant sections presenting the cuttings dispersion model. However, this scenario represents the maximum cumulative area in which a single cell of the model exceeded the control limit at any point during the 45-day simulation. It does not represent a continuous impact, nor does it represent an environmental burden.

Any such impact is expected to be temporary, reversible and limited to the discharge period and the short dispersion phase following discharge. The modelling concludes that environmental risks in the water column are expected to cease within a few days after the end of discharges from the well. Overall, there may be a temporary transboundary impact on marine water quality; however, this is expected to be short-term, be confined to the water column and not be associated with persistent contamination of sediments or long-term impacts on Italian waters.

#### 10.4.2.2 Seabed

---

Disturbance to the seabed has been assessed in relation to the installation of the riser, well drilling, cementing operations, the disposal of permitted drill cuttings and the temporary placement of subsea equipment. These activities result in an extremely localised physical disturbance confined to the immediate vicinity of the well site. The resuspension of sediments caused by drilling and the jetting of water to install the riser is expected to settle rapidly near the wellhead, whilst no dredging, dredging of the seabed or permanent infrastructure on the seabed.

Numerical modelling during drilling indicates that no transboundary impacts on seabed sediments within the Italian EEZ are expected. The predicted significant sediment risk is extremely localised around the discharge point, with a maximum extent of approximately 283 m during Season 1 (October to March) and 397 m during Season 2 (April to September). The simulated exceedances of the sediment sorting limit remained within the Greek EEZ in both scenarios assessed.

**Figure 10-12: Cumulative simulated exceedances of the sediment sorting limit in relation to the boundaries of the Greek and Italian EEZs**

Consequently, no significant cross-border impacts on seabed morphology or benthic habitats are anticipated. Overall, no significant cross-border impact on Italian seabed sediments is anticipated.

#### 10.4.2.3 Underwater noise

Sound propagates effectively in the marine environment and may affect highly mobile marine species capable of crossing national maritime borders. Sources of noise include dynamic positioning thrusters, drilling equipment, support vessel operations, ROV activities and vertical seismic profiling (VSP).

The assessment took into account the temporary and intermittent nature of these activities, the relatively low noise levels during drilling operations compared with other offshore activities, and the mobility of marine fauna. Although individual animals may temporarily avoid the immediate vicinity of the drilling rig, no population-level impacts or significant transboundary impacts are anticipated. The underwater noise

generated during drilling operations attenuates with distance and is not expected to cause biologically significant impacts on a transboundary scale.

#### 10.4.2.4 Air quality

---

Atmospheric emissions have been identified as a potential transboundary pathway, as combustion emissions from the floating drilling unit, support vessels, helicopters and onshore supply activities may be dispersed over significant distances, depending on prevailing meteorological conditions. The assessment took into account emissions of greenhouse gases and other atmospheric pollutants, including nitrogen oxides, sulphur oxides, carbon monoxide and particulate matter.

The exploratory drilling campaign will be temporary, and the main sources of emissions will be located offshore, at a considerable distance from coastal receptors. Emissions from the floating drilling rig, support vessels and helicopters will disperse rapidly over the open sea under prevailing meteorological conditions, reducing the likelihood of measurable changes in air quality beyond the immediate operational area. Furthermore, emission levels are limited by the short duration of the drilling campaign, the use of marine fuels that comply with current sulphur content requirements, and the absence of regular combustion sources, such as gas flaring, gas venting or combustion sources associated with production. Consequently, no significant transboundary impacts on air quality are expected.

Greenhouse gas emissions will gradually contribute to global climate change, but do not cause a discernible or measurable impact on air quality in the territory of a neighbouring state.

#### 10.4.2.5 Maritime and air traffic

---

The project's vessels will operate within an area used by international commercial shipping in the northern Ionian Sea. Activities include the mobilisation (mob) and demobilisation (de-mob) of the floating drilling unit, the routine operations of supply vessels, the activities of standby vessels and the occasional presence of specialised support vessels. Temporary interactions with existing shipping lanes will be managed through the establishment of the 500-metre safety zone required by law, Notices to Mariners, NAVTEX broadcasts and standard maritime navigation procedures.

Given that the movements of the vessels will be temporary and will represent a minor addition to existing commercial shipping in the northern Ionian Sea, no significant cross-border impacts on international shipping are expected.

Helicopter flights include regular crew rotations, the delivery of critical equipment and emergency flights between Corfu International Airport and the offshore drilling rig. The frequency of flights is expected to remain relatively low and will generally follow established air routes and operational procedures. Helicopter flights will be limited in number, short in duration and directed exclusively to the offshore drilling unit. Consequently, helicopter flights are not expected to cause any transboundary environmental impacts.

#### 10.4.2.6 Waste generation and management

All waste streams generated in the offshore area will be sorted on board, temporarily stored, transported to the onshore support base at the Port of Igoumenitsa, and subsequently transported by licensed contractors to authorised treatment, recovery or disposal facilities, in accordance with the Project's Waste Management Plan and the applicable legislation. There will be no deliberate discharge of waste beyond the permitted operational discharges regulated by the MARPOL Convention, and no cross-border transport of waste from the Project is envisaged. Consequently, routine waste management activities are not expected to cause any transboundary environmental impacts.

#### 10.4.2.7 Accidental hydrocarbon spill

The main mechanism through which transboundary environmental impacts could arise would be via low-probability accidental events, in particular a significant hydrocarbon spill. Such scenarios have been assessed separately using specific oil spill modelling presented in Chapter 9. Although the probability of accidental events is very low, the assessment took into account scenarios involving marine diesel spills, chemical spills and loss of control of the wells, recognising that under certain combinations of wind, waves and currents, pollutants could potentially be carried beyond the Greek EEZ. Consequently, the scenarios were assessed separately on the basis of a precautionary approach, supported by oil spill modelling where appropriate, and taking into account the Project's preventive measures, well integrity systems, emergency response arrangements and the oil spill contingency plan. These assessments take into account potential spill trajectories, prevailing oceanographic conditions and response capabilities in accordance with recognised international practice.

With regard to the scenario of an instantaneous surface spill of marine gas oil (MGO) presented in section 10.2.3.1.1, the modelling indicates that any potential transboundary impacts would be limited and short-term. The movement of oil on the surface may occur in different directions depending on seasonal winds and currents; however, the highest probability of occurrence remains close to the site of the spill, and the affected area is limited due to the rapid degradation and evaporation of MGO.

Coastal pollution is predicted as a possibility outside Greek waters, with a low probability. In Phase 1, coastal pollution may occur in five countries between Croatia and Greece, whilst in Phase 2 it may occur in four countries. The highest predicted probability of coastal pollution is observed in Italy, reaching 5 per cent in Season 1 and 12.2 per cent in Season 2. The shortest predicted time to reach the coast is 2.8 days in Italy during Season 1. In all the above cases, the potential pollution at the percentages mentioned is expected only if no mitigation measures are taken, which in practice cannot happen, as the regulatory framework imposes a strong legal obligation to draw up an Emergency Response Plan (ERP), which must be submitted to the competent authorities for assessment and approval.

Overall, the MGO surface spill scenario is likely to cause limited cross-border impacts; however, these will be short-term, of short duration and significantly less severe than scenarios involving a prolonged release of hydrocarbons.

# 11 Addressing environmental and social impacts

## 11.1 Introduction

The environmental and social impact assessment presented in Chapter 10 identified and evaluated the potential environmental and social impacts associated with the proposed exploration drilling programme. Based on the findings of that assessment, a range of measures has been developed to prevent, minimise and manage adverse impacts throughout the Project lifecycle.

Wherever practicable, environmental and social considerations have been incorporated into the Project design through embedded mitigation measures. These are complemented by operational controls and good management practices that will be implemented during Project execution to further prevent or minimise potential impacts.

In addition to the mitigation measures for routine Project activities, this chapter presents the key prevention and mitigation measures applicable to major accident hazards, measures to enhance the Project's resilience to climate change, and an overview of the Emergency Response Plan (ERP)<sup>67</sup>.

The implementation and effectiveness of these measures will be verified, where appropriate, through the Environmental Monitoring Programme (EMP) presented in Chapter 12.

## 11.2 Proposed measures for normal / routine project activities

### 11.2.1 Proposed measures during drilling preparation and mobilisation phase

The measures for the prevention, minimisation and management of potential environmental and social impacts during the drilling preparation and mobilisation phase are presented in Table 11-1.

During this phase, activities will be undertaken in a manner that minimises environmental and social impacts through the implementation of embedded design measures, operational controls and good management practices. The mitigation measures (MM1) apply to the establishment of the temporary logistics base, installation of the temporary helicopter hangar, mobilisation of the Mobile Offshore Drilling Unit (MODU), support vessels, personnel and equipment, and completion of the pre-drilling activities.

<sup>67</sup> Energean Hellas Ltd, Drilling Emergency Response Plan. Document No: GRC-BL2-PL-HSE-0004

**Table 11-1: Proposed mitigation measures for potential adverse environmental and social impacts during the drilling preparation and mobilisation phase of the project**

| ENVIRONMENTAL PARAMETERS                 | OBJECTIVE OF MEASURE                                          | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Climatic and Bioclimatic Characteristics | Minimise greenhouse gas emissions and air pollutant emissions | 55. Each Project Contractor shall maintain all machinery, vessels, and vehicles used in the Project according to manufacturer specifications to reduce exhaust emissions. Maintenance shall be carried out by the relevant contractor/owner in accordance with manufacturer schedules, at licensed onshore facilities where practicable.                                                                                                                                                                                                                  |
|                                          |                                                               | 56. The MODU and all support vessels shall comply with the requirements of MARPOL 73/78 Convention, Annex VI "Regulations for the Prevention of Air Pollution from Ships". Annex VI regulates emissions of ozone-depleting compounds, nitrogen oxides (NOX), sulfur oxides (SOx) and volatile organic compounds (VOCs).                                                                                                                                                                                                                                   |
|                                          |                                                               | 57. Energean shall coordinate with relevant Contractors, the Port Authority and Corfu International Airport to optimise support vessel and helicopter logistics through careful voyage planning, taking into account rig operational requirements, so as to minimise the number of vessel trips, reduce the duration of activities within the project area, and avoid unnecessary engine operation and idling, to the extent achievable within the operational constraints of each party involved.                                                        |
|                                          |                                                               | 58. Energean shall assess, in coordination with the Port of Igoumenitsa operator and relevant vessel operators, the feasibility of using existing shore-power facilities for Project vessels while alongside. Shore power may be used where existing infrastructure is available and compatible with the vessel, and where the necessary technical, safety, operational and commercial arrangements have been agreed between the relevant parties. The Project does not include installation or substantial upgrading of port shore-power infrastructure. |
|                                          |                                                               | 59. Use LED lighting for interior lighting, where practicable, and avoid unnecessary operation of external lighting.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| ENVIRONMENTAL PARAMETERS                                 | OBJECTIVE OF MEASURE                                                                | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Morphological and Landscape Characteristics              | Minimise impacts on landscape characteristics, visual amenity and seabed morphology | 60. The Project shall use existing facilities within the Port of Igoumenitsa and Corfu International Airport. No new permanent onshore or offshore infrastructure, dredging, land reclamation or quay modifications shall be required. All activities shall remain within designated operational areas.                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                          |                                                                                     | 61. Onshore Project support activities at the Port of Igoumenitsa and Corfu International Airport shall be undertaken within the areas allocated or agreed for Project use by the relevant facility operator. Project equipment, materials, vehicles and wastes shall be stored, handled and parked only within designated areas, except when being transported in accordance with applicable logistics and waste-management arrangements. Unauthorised disposal or storage outside the designated Project areas shall be prohibited.                                                                                                                                                     |
|                                                          |                                                                                     | 62. The Project shall use the existing surfaced areas of the onshore logistics base, and no additional permanent impermeable surfacing is planned. If additional surfacing is subsequently required for safe Project operations, it shall be limited to the minimum necessary extent within the area allocated for Project use and shall be subject to prior agreement with the Port operator and any applicable approvals. Any reinstatement requirements shall be agreed with the Port operator.                                                                                                                                                                                        |
| Geological, Tectonic and Soil / Sediment Characteristics | Protect soil /sediment and prevent physical disturbance and contamination           | 63. Hazardous and non-hazardous wastes generated offshore shall be segregated, stored, handled and transferred to authorised shore reception or waste-management facilities in accordance with the Project Waste Management Plan and the applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. No solid or hazardous waste shall be intentionally discharged to the marine environment. Operational discharges, including drilling fluids and cuttings, sewage, bilge water, ballast water and food waste, shall be managed in accordance with the relevant discharge-specific measures and applicable legal requirements. |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                            | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                 | 64. Fuel, chemicals and hazardous materials (identified as such under applicable legislation or the relevant Safety Data Sheet) shall be stored in designated areas within the logistics base, equipped with secondary containment and segregation appropriate to the nature, quantity and spill risk of the materials. Suitable spill response materials and equipment shall be readily available at relevant storage, transfer and handling locations, in accordance with applicable site procedures and Project spill-response arrangements.                                                                |
| Air quality              | Protect ambient air quality by minimising atmospheric emissions | 65. Logistics activities, including support vessel operations and the use of onshore vehicles and machinery, shall be planned and managed by the relevant Contractors, in coordination with Energean and the facility operators, to minimise unnecessary engine operation, idling and associated atmospheric emissions, to the extent achievable within operational and scheduling constraints.                                                                                                                                                                                                                |
| Noise and Vibrations     | Minimise underwater and airborne noise and protect marine fauna | <p>66. Material handling and cargo operations at the logistics base shall be undertaken by the relevant Contractors in accordance with the Port of Igoumenitsa operating procedures, using equipment maintained in good working order to minimise unnecessary noise emissions.</p> <p>67. Support vessel operations shall be coordinated by Energean, in collaboration with the relevant Contractors, taking account of the facility operator, vessel and rig operational and safety requirements, to minimise underwater noise and unnecessary engine operation and idling, where reasonably practicable.</p> |

| ENVIRONMENTAL PARAMETERS                                 | OBJECTIVE OF MEASURE                                                              | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Seawater                                                 | Protect seawater quality                                                          | <p>68. Offshore-generated hazardous and non-hazardous wastes (identified as such under applicable legislation or the relevant Safety Data Sheet) shall be managed in accordance with the Waste Management Plan and applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. Operational discharges shall be managed in accordance with the requirements applicable to each discharge stream, including MARPOL, the BWM Convention, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation, as relevant. Chemical selection, use and discharge shall be controlled through the Chemical Use Plan.</p> |
| Marine life, Flora, fauna, habitats, and protected areas | Protect marine fauna, and protected species by avoiding or minimising disturbance | <p>69. A Marine Mammal Mitigation Plan (MMMP) shall be prepared prior to the commencement of non-impulsive sound emissions. The MMMP shall set out the mitigation protocol to be implemented by the relevant contractors for the Vertical Seismic Profile (VSP) operation, including visual monitoring by a qualified Marine Mammal Observer (MMO) and, where applicable, Passive Acoustic Monitoring (PAM), to detect marine mammals and manage the risk of injury from impulsive noise prior to and during the VSP.</p>                                                                                                                                                                  |
|                                                          |                                                                                   | <p>70. Project-related vessels shall operate at speeds not exceeding 14 knots, or their maximum operational speed where lower, within areas identified in the Marine Mammal Mitigation Plan as having higher marine mammal presence, without compromising vessel safety or emergency response capability.</p>                                                                                                                                                                                                                                                                                                                                                                              |
|                                                          |                                                                                   | <p>71. Vessels shall maintain a safe distance from any observed marine mammal, avoid approaching it head-on, avoid crossing or waiting ahead of its direction of travel, and, where safe and practicable, steer behind its path.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| ENVIRONMENTAL PARAMETERS  | OBJECTIVE OF MEASURE                                                                                                      | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           |                                                                                                                           | <p>72. In the event of a collision between a Project vessel and a marine mammal or sea turtle, the vessel's Master shall immediately report the incident to Energean in accordance with the Project's incident-reporting procedure. Energean shall, as soon as reasonably practicable and within any applicable regulatory timeframe, formally notify the competent environmental and other relevant authorities, as required by applicable legislation.</p> <p>73. Established transit routes shall be followed by Project vessels, where practicable, during drilling preparation and mobilisation, in accordance with standard vessel transit procedures, including applicable navigational notifications (e.g., NAVTEX) and coordination with the competent maritime authorities, and subject to the Master's discretion on safety grounds.</p> <p>74. Prior to spudding the well, a remotely operated vehicle (ROV) survey shall be conducted within a 70-metre radius of the planned wellhead location to inspect the seabed for pre-existing features or sensitivities. If any previously unidentified seabed features or sensitivities are observed within the surveyed area, the relevant authorities shall be informed.</p> |
| Spatial Planning Land Use | Minimise interference with existing onshore land uses and ensure compliance with applicable spatial planning requirements | 75. Project activities shall be conducted in accordance with the terms of existing operating permits, licenses and land use designations applicable to the Port of Igoumenitsa and Corfu International Airport, and shall not require any change to current spatial planning designations for these areas.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Maritime uses             | Minimise impacts on maritime uses                                                                                         | 76. Prior to mobilisation and demobilisation, the Operator shall ensure that the drilling contractor engages with the Hellenic Navy Hydrographic Service regarding the planned drilling and vessel-transit operations, in accordance with standard rig mobilisation procedures. The charting review and the ESSBS confirm that no submarine cables are present within 500 metres of the drilling location.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                      | <p>77. The main operators of cruise ships and LNG carriers identified through the Shipping and Navigation Assessment as regularly passing within or near 500 m of the site shall be provided with advance notice of the Asopus-1 operations. This notice shall supplement applicable official navigational notifications, including NAVTEX messages and Notices to Mariners, enabling the vessel operators to review or amend their passage plans, if required.</p>               |
|                          |                      | <p>78. The OIM/Master of the MODU and the Master of each support vessel shall have overriding authority and responsibility to make decisions with respect to safety and pollution prevention, in accordance with the ISM Code. The MODU and Project support vessels will comply with applicable international and national maritime legal requirements, including COLREGs (Ref. ii) and the display of appropriate lights, shapes and signals.</p>                                |
|                          |                      | <p>79. Project support vessels shall be scheduled and operationally coordinated by the Project logistics team. The owners and/or operators of the Platform Supply Vessels shall be responsible for ensuring that each vessel displays the applicable lights and marks and operates AIS, where required, and complies with applicable international, Flag-State, and coastal-State requirements, including applicable Greek legislation, COLREGs (Ref. ii) and SOLAS (Ref. x).</p> |
|                          |                      | <p>80. Subject to authorisation by the competent Greek authorities, a 500 m safety zone around the MODU will be established and notified for the duration of well operations. Unauthorised vessel access to the safety zone will be restricted in accordance with the applicable authorisation and maritime notices. The PSVs will assist the MODU in monitoring the safety zone and communicating with approaching vessels, as required, whilst on site.</p>                     |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                                                                        | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|-------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                             | <p>81. Information on the establishment and duration of the safety zone, and relevant details of the operation, shall be disseminated through official maritime-safety information channels, including NAVTEX messages, navigational warnings, and, where applicable, Notices to Mariners, issued or coordinated by the Hellenic Navy Hydrographic Service in cooperation with the competent Hellenic Coast Guard authorities.</p>                                                                                                                                                                                                                                          |
| Cultural heritage        | Protect underwater cultural heritage and ensure appropriate management of chance archaeological discoveries | <p>82. All project activities shall be governed principally by Law 4858/2021 (Code of Legislation for the Protection of Antiquities and Cultural Heritage) and informed by the principles of the UNESCO Convention on the Protection of the Underwater Cultural Heritage (2001) to ensure the appropriate management and, where practicable, in situ preservation of submerged archaeological resources.</p>                                                                                                                                                                                                                                                                |
|                          |                                                                                                             | <p>83. Prior to the commencement of drilling activities, the Company shall submit to the Hellenic Ephorate of Underwater Antiquities the results of the detailed seabed survey of the marine area at the proposed Asopus-1 well location for review with respect to the potential presence of underwater cultural heritage. Based on the results of this review, and if deemed necessary by the Ephorate, an on-site underwater archaeological survey using technology (ROV, SSS, Sub bottom profiler) shall be provided in the marine area where the exploration drilling is planned to take place. The cost of conducting this survey must be covered by the Company.</p> |
|                          |                                                                                                             | <p>84. Any additional geophysical, environmental or engineering datasets acquired before drilling that provide materially relevant new seabed information for areas subject to planned Project disturbance shall be reviewed to determine whether they materially change the archaeological baseline or require further archaeological assessment and/or notification to the Competent Authority.</p>                                                                                                                                                                                                                                                                       |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                    | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                         | 85. Prior to the commencement of drilling activities, relevant findings and applicable requirements from the archaeological assessment shall be communicated to personnel responsible for planning, supervising or conducting Project activities involving seabed interaction.                                                                                                                                                                                                                                                                                                                                    |
|                          |                                         | 86. Project personnel engaged in activities involving seabed interaction or subsea observation shall be informed of the applicable cultural heritage controls and made aware of the procedures to follow in the event of a suspected discovery. In the event of a suspected archaeological discovery within the area of the Asopus -1 well location, the relevant Contractor shall implement the actions assigned under the Chance Find Procedure, including stopping any activity under its control that could disturb the suspected find and promptly reporting it through the defined Project reporting route. |
| Economic Activities      | Minimise impacts on economic activities | 87. The Project shall actively identify and engage with capable local and other Greek suppliers and service providers for logistics, port services, and other support activities where they meet the Project's safety, operational, and commercial requirements.                                                                                                                                                                                                                                                                                                                                                  |
|                          |                                         | 88. Regular and timely communication shall be maintained with the Hellenic Coast Guard, relevant fisheries organisations, the Port Authorities of Igoumenitsa and Corfu, Corfu International Airport operator, and other identified key stakeholders throughout mobilisation.                                                                                                                                                                                                                                                                                                                                     |
|                          |                                         | 89. Where practicable, mobilisation logistics at the Port of Igoumenitsa shall be scheduled in coordination with the Port Authority to minimise disruption to routine port commercial and passenger operations.                                                                                                                                                                                                                                                                                                                                                                                                   |
|                          |                                         | 90. Advance notification of the planned drilling campaign and its indicative timing shall be provided to local fishing associations and tourism/port stakeholders to support their own operational planning.                                                                                                                                                                                                                                                                                                                                                                                                      |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                                       | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Community H&S            | Protect the community health, safety and welfare of workers and the public | 91. Appropriate Personal Protective Equipment (PPE) shall be provided and used by all personnel, where required by the task and work area, in accordance with site procedures at the onshore logistics base and during marine operations. Each Project contractor and company shall be responsible for ensuring its personnel comply with the Project's PPE requirements.                                                                                                                                               |
|                          |                                                                            | 92. Each Project company and contractor shall maintain appropriate training and competence systems for its personnel and shall ensure that personnel have the skills, qualifications and risk awareness necessary to perform the activities assigned to them. Personnel shall receive project-specific briefings on marine operations, traffic management and emergency response, as applicable. Lifting operations shall be carried out by the appropriate contractor with the required competence and qualifications. |
|                          |                                                                            | 93. Emergency response drills, including fire, medical evacuation, man overboard and oil spill response exercises, shall be conducted at intervals defined in the Project and vessel emergency response procedures, and in accordance with applicable legal and Flag-State requirements.                                                                                                                                                                                                                                |
|                          |                                                                            | 94. The Onshore Traffic Management Plan shall be updated by the relevant Contractors, reviewed by Energean and the Port Authority, and used as the basis for the detailed site-specific plan to be implemented prior to mobilisation. The plan shall control vehicle movements, signage and site access.                                                                                                                                                                                                                |
|                          |                                                                            | 95. Mobilisation of the MODU and support vessels shall be coordinated with the competent maritime authorities, including the Hellenic Navy Hydrographic Service and Hellenic Coast Guard, with advance issuance of Notices to Mariners and NAVTEX broadcasts, as applicable, prior to transit and positioning.                                                                                                                                                                                                          |
|                          |                                                                            | 96. Installation of the temporary helicopter hangar and associated helicopter operations at Corfu International Airport shall comply with applicable civil aviation safety procedures and airport operator requirements and shall be coordinated with the relevant airport authorities.                                                                                                                                                                                                                                 |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                                                      | MITIGATION MEASURES DURING DRILLING PREPARATION & MOBILISATION                                                                                                                                                              |
|--------------------------|-------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical Infrastructure | Avoid disruption to maritime, energy, telecommunications and environmental infrastructure | 97. Project activities at the Port of Igoumenitsa shall be undertaken in accordance with the applicable Environmental Terms (Ref. No. 139663103448/08/01.06.2009, as amended and in effect at the time of this assessment). |

### 11.2.2 Proposed Measures during Drilling Operations

The measures for the prevention, minimisation and management of potential environmental and social impacts during the exploration drilling operations phase are presented in the following Table.

During the drilling operations phase, activities will be undertaken in accordance with applicable regulatory requirements, Good International Industry Practice (GIIP) and Project-specific operational procedures to minimise environmental and social impacts. The mitigation measures (MM2) presented apply to drilling of the exploration well, routine offshore operations, support vessel and helicopter activities, and the management of drilling fluids, discharges, chemicals and wastes.

**Table 11-2: Proposed mitigation measures for potential adverse environmental and social impacts during the drilling operations**

| ENVIRONMENTAL PARAMETERS                 | OBJECTIVE OF MEASURE                                          | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Climatic and Bioclimatic Characteristics | Minimise greenhouse gas emissions and air pollutant emissions | <b>MM2-72</b> Each Project Contractor shall maintain all machinery, vessels, and vehicles used in the Project according to manufacturer specifications to reduce exhaust emissions. Maintenance shall be carried out by the relevant contractor/owner in accordance with manufacturer schedules, at licensed onshore facilities where practicable.                                                                                                                                                  |
|                                          |                                                               | <b>MM2-73</b> The MODU and all support vessels shall comply with the requirements of MARPOL 73/78 Convention, Annex VI "Regulations for the Prevention of Air Pollution from Ships". Annex VI regulates emissions of ozone-depleting compounds, nitrogen oxides (NOX), sulfur oxides (SOx) and volatile organic compounds (VOCs).                                                                                                                                                                   |
|                                          |                                                               | <b>MM2-74</b> Energean shall coordinate with Contractors, the Port Authority and Corfu International Airport to optimise support vessel and helicopter logistics through careful voyage planning, taking into account rig operational requirements, so as to minimise the number of vessel trips, reduce the duration of activities within the project area, and avoid unnecessary engine operation and idling, to the extent achievable within the operational constraints of each party involved. |
|                                          |                                                               | <b>MM2-75</b> Use LED lighting for interior lighting, where practicable, and avoid unnecessary operation of external lighting.                                                                                                                                                                                                                                                                                                                                                                      |

| ENVIRONMENTAL PARAMETERS                                 | OBJECTIVE OF MEASURE                                                                | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Morphological and Landscape Characteristics              | Minimise impacts on landscape characteristics, visual amenity and seabed morphology | <b>MM2-76</b> Onshore Project support activities at the Port of Igoumenitsa and Corfu International Airport shall be undertaken within the areas allocated or agreed for Project use by the relevant facility operator. Project equipment, materials, vehicles and wastes shall be stored, handled and parked only within designated areas, except when being transported in accordance with applicable logistics and waste-management arrangements. Unauthorised disposal or storage outside the designated Project areas shall be prohibited.                                                                                                                                                                                                                                        |
|                                                          |                                                                                     | <b>MM2-77</b> The Project shall use the existing surfaced areas of the onshore logistics base, and no additional permanent impermeable surfacing is planned. If additional surfacing is subsequently required for safe Project operations, it shall be limited to the minimum necessary extent within the area allocated for Project use and shall be subject to prior agreement with the Port operator and any applicable approvals. Any reinstatement requirements shall be agreed with the Port operator.                                                                                                                                                                                                                                                                           |
|                                                          |                                                                                     | <b>MM2-78</b> While conducting well operations at the Asopus-1 location, the MODU shall maintain station using a dynamic positioning system meeting IMO DP Equipment Class 3 requirements or an equivalent Class 3 notation accepted by the relevant Flag State and classification society. No anchoring is planned for routine station-keeping.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Geological, Tectonic and Soil / Sediment Characteristics | Protect soil /sediment and prevent physical disturbance and contamination           | <b>MM2-79</b> Hazardous and non-hazardous waste (identified as such under applicable legislation or the relevant Safety Data Sheet) generated offshore shall be segregated, stored, handled and transferred to authorised shore reception or waste-management facilities in accordance with the Project Waste Management Plan and the applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. No solid or hazardous waste shall be intentionally discharged to the marine environment. Operational discharges, including drilling fluids and cuttings, sewage, bilge water, ballast water and food waste, shall be managed in accordance with the relevant discharge-specific measures and applicable legal requirements. |
|                                                          |                                                                                     | <b>MM2-80</b> Fuel, chemicals and hazardous materials (identified as such under applicable legislation or the relevant Safety Data Sheet) stored at the onshore logistics base shall be kept in designated areas with secondary containment and segregation appropriate to the nature, quantity and spill risk of the materials. Suitable spill response materials and equipment shall be readily available at relevant storage, transfer and handling locations, in accordance with applicable site procedures and Project spill-response arrangements.                                                                                                                                                                                                                               |
|                                                          |                                                                                     | <b>MM2-81</b> Drilling fluids, cuttings and chemicals shall be managed in accordance with the Project Chemical Use Plan, Waste Management Plan, assessed discharge arrangements and applicable regulatory requirements. Water-based muds will be used, with no planned use of oil-based or non-aqueous drilling fluids. Preference is given to PLONOR substances, CHARM Gold products or OCNS Group E products, as applicable, where operationally suitable and available. Other chemicals may be used where required for planned or contingency operations, provided their suitability has been reviewed, and no suitable lower-hazard alternative is reasonably available.                                                                                                           |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                            | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                 | <b>MM2-82</b> Cementing discharges shall be managed according to the Chemical Use Plan, assessed discharge arrangements, applicable regulatory requirements and, where relevant, the Waste Management Plan. Preference is given to cementing chemicals comprising PLONOR substances or classified as CHARM Gold or OCNS Group E, as applicable, where operationally suitable and available. Other chemicals may be used where required for planned or contingency cementing operations, provided their suitability has been reviewed, and no suitable lower-hazard alternative is reasonably available.                                       |
| Air quality              | Protect ambient air quality by minimising atmospheric emissions | <b>MM2-83</b> Drilling activities shall be planned and managed by the Drilling Contractor to minimise unnecessary engine operation, idling and associated atmospheric emissions.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Noise and Vibrations     | Minimise underwater and airborne noise and protect marine fauna | <b>MM2-84</b> Material handling and cargo operations at the logistics base shall be undertaken by the relevant Contractors in accordance with applicable Port of Igoumenitsa operating procedures, using equipment maintained in good working order to minimise unnecessary noise emissions.                                                                                                                                                                                                                                                                                                                                                  |
|                          |                                                                 | <b>MM2-85</b> Routine inspection and maintenance of the drillship, support vessels, helicopters, generators and relevant noise-generating mechanical equipment shall be undertaken in accordance with applicable maintenance programmes and manufacturers' recommendations, minimising unnecessary noise and vibration emissions.                                                                                                                                                                                                                                                                                                             |
|                          |                                                                 | <b>MM2-86</b> Support vessel operations shall be coordinated by Energean, in collaboration with the relevant Contractors, taking account of the facility operator, vessel and rig operational and safety requirements, to minimise underwater noise and unnecessary engine operation and idling, where reasonably practicable.                                                                                                                                                                                                                                                                                                                |
|                          |                                                                 | <b>MM2-87</b> All Vertical Seismic Profiling (VSP) operations shall commence with a soft start (ramp-up), gradually increasing acoustic energy from low to full operational power over 20–30 minutes, in accordance with the Marine Mammal Mitigation Plan. The duration of VSP operations shall be limited to that reasonably necessary to achieve the survey objectives.                                                                                                                                                                                                                                                                    |
| Seawater                 | Protect seawater quality                                        | <b>MM2-88</b> Offshore-generated hazardous and non-hazardous wastes shall be managed in accordance with the Waste Management Plan and applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. Operational discharges shall be managed in accordance with the requirements applicable to each discharge stream, including MARPOL, the BWM Convention, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation, as relevant. Chemical selection, use and discharge shall be controlled through the Chemical Use Plan.                                     |
|                          |                                                                 | <b>MM2-89</b> A Chemical Use Plan shall be implemented, which shall include: (i) the chemicals proposed for planned and contingency operations and relevant environmental hazard and ecotoxicity information; (ii) the purpose or purposes for which the chemicals are intended to be used; (iii) the estimated concentrations and quantities of the chemicals intended to be used; (iv) the potential routes and locations through which chemicals may be discharged to the marine environment, as applicable. Chemical selection shall take account of operational requirements and the availability of suitable lower-hazard alternatives. |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                      | <p><b>MM2-90</b> Only chemicals required for drilling, cementing and associated well operations, together with chemicals required for routine vessel and equipment operations, will be used offshore. No well-completion, stimulation or production-related chemicals are planned.</p> <p><b>MM2-91</b> Chemical selection will follow the principles of avoid, substitute, minimise and control to reduce potential risks to seawater quality. Preference will be given to PLONOR substances and CHARM Gold or OCNS Group E products, as applicable, where operationally suitable and reasonably available. Other chemicals may be selected where required for planned or contingency operations following review of their suitability and available lower-hazard alternatives.</p> <p><b>MM2-92</b> The use and discharge of substances covered by Annex I of the Offshore Protocol shall be prohibited, except where permitted under the applicable regulatory framework. Chemicals with higher-hazard classifications will be used only where required for a specific technical function and where no suitable lower-hazard alternative is reasonably available.</p> <p><b>MM2-93</b> Pipe dope and casing dope will be treated as non-discharged chemicals, with application controlled to minimise excess material and prevent planned discharge to sea.</p> <p><b>MM2-94</b> Chemical transfer, storage and handling offshore will be controlled through containment, spill prevention, bunding, or closed drainage where applicable, trained personnel and inventory management, taking account of the nature, quantity and spill risk of the chemicals.</p> <p><b>MM2-95</b> Drilling cuttings and water-based drilling fluids discharged at the seabed during the riserless sections shall be managed in accordance with applicable regulatory requirements, including the Barcelona Convention Offshore Protocol and the relevant UNEP/MAP Common Standards and Guidelines for the use and disposal of drilling fluids and cuttings in the Mediterranean.</p> <p><b>MM2-96</b> Drilling cuttings and associated drilling fluids generated after installing the riser shall be managed in accordance with applicable regulatory requirements, including the Barcelona Convention Offshore Protocol and the relevant UNEP/MAP Common Standards and Guidelines for the use and disposal of drilling fluids and cuttings in the Mediterranean. Drilling returns shall be monitored through LWD, mudlogging and routine observation. Where cuttings or drilling returns are identified as mixed with reservoir hydrocarbons in concentrations that make them unsuitable for discharge under applicable requirements, discharge of the affected material shall cease. The affected cuttings and fluids shall be contained onboard and transferred ashore for management at an authorised facility.</p> <p><b>MM2-97</b> Sanitary wastewater (blackwater and greywater) shall be managed and discharged in accordance with the requirements of MARPOL Annex IV and applicable Greek legislation. Blackwater shall be treated in an approved sewage treatment system prior to discharge. Where applicable discharge requirements cannot be achieved, sewage shall be retained in holding tanks and either discharged once the requirements can be met or transferred to authorised shore reception facilities.</p> |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                      | <b>MM2-98</b> Bilge water collected from machinery spaces shall be routed to dedicated bilge holding tanks and processed through an approved oily water separator (OWS) equipped with a certified oil content monitor and automatic stopping device. Treated bilge water may only be discharged when the oil content of the undiluted effluent does not exceed 15 mg/L (15 ppm) and all other applicable MARPOL Annex I discharge conditions are met.                                                                                                                                |
|                          |                      | <b>MM2-99</b> Deck drainage from non-hazardous areas shall be discharged through the vessel drainage system. Any tainted runoff shall be contained and managed through the vessel's applicable drainage and treatment arrangements, including the oily water separator (OWS), if applicable. Where oily drainage is treated through an OWS, the oil content of any discharge shall not exceed 15 mg/L (15 ppm). Deck drainage may only be discharged to sea where permitted under applicable MARPOL, Flag State and vessel requirements and where no visible oil sheen would result. |
|                          |                      | <b>MM2-100</b> Cooling water shall be discharged through multiple outlets. The temperature difference between cooling-water intake and discharge shall not exceed 5 °C. Cooling-water discharges shall be managed in accordance with the MODU's approved systems and procedures and applicable environmental requirements. The discharge shall comprise non-contact seawater and shall not contain oil or harmful substances.                                                                                                                                                        |
|                          |                      | <b>MM2-101</b> Ballast water on the MODU and support/supply vessels shall be managed in accordance with the Ballast Water Management Convention, including the applicable provisions of Regulations B-1 and D-1/D-2, as applicable, the approved Ballast Water Management Plan, and the Ballast Water Record Book. Any ballast water management system installed on board shall be type-approved in accordance with Regulation D-3.                                                                                                                                                  |
|                          |                      | <b>MM2-102</b> Any unused, excess, or waste pipe dope, tainted rags or absorbents, and empty containers shall be collected, segregated and managed in accordance with the Project Waste Management Plan and applicable MARPOL requirements, and transferred via the supply base to authorised onshore waste-management facilities. Any accidental spills will be managed in accordance with the Project spill response procedures. Use of pipe dope shall be subject to the Chemical Use Plan, and pipe dope shall not be intentionally discharged to seawater.                      |
|                          |                      | <b>MM2-103</b> Brine streams may only be discharged where they do not contain oil or harmful substances and in accordance with applicable MARPOL requirements, Greek environmental legislation, permit conditions and vessel procedures.                                                                                                                                                                                                                                                                                                                                             |
|                          |                      | <b>MM2-104</b> Food waste shall be comminuted or ground to pass through a screen with openings no greater than 25 mm and may only be discharged in accordance with the location and operational conditions applicable to the MODU and Project vessels under MARPOL Annex V, including the applicable minimum distance from the nearest land. Food waste mixed with other waste shall not be discharged.                                                                                                                                                                              |

| ENVIRONMENTAL PARAMETERS                    | OBJECTIVE OF MEASURE                                                              | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Flora, fauna, habitats, and protected areas | Protect marine fauna, and protected species by avoiding or minimising disturbance | <b>MM2-105</b> Before commencing VSP operations, certified Marine Mammal Observers (MMOs) shall conduct a pre-shooting visual search for marine mammals and sea turtles within the 500 m zone specified in the Marine Mammal Mitigation Plan. Passive Acoustic Monitoring (PAM) shall supplement visual monitoring for vocalising marine mammals during darkness or poor visibility. The duration of the pre-shooting search, ramp-up (soft-start) procedure, and the delay, shutdown and restart criteria shall be implemented in accordance with the Marine Mammal Mitigation Plan and applicable regulatory requirements.                                                                                                                                                |
|                                             |                                                                                   | <b>MM2-106</b> During VSP operations, two Marine Mammal Observers (MMOs), holding ACCOBAMS certification or an equivalent recognised qualification, shall be deployed at suitable observation points onboard the vessel to provide effective visual coverage of the 500 m mitigation zone. One or more suitably qualified PAM operators shall be provided, as required by the Marine Mammal Mitigation Plan, to implement monitoring during darkness or poor visibility. Marine mammal and sea turtle sightings, pre-shooting searches, delays, soft-starts, shutdowns and other mitigation actions shall be recorded using the applicable reporting forms and submitted in accordance with the Marine Mammal Mitigation Plan and applicable permit/reporting requirements. |
|                                             |                                                                                   | <b>MM2-107</b> All acoustic source tests shall commence with a soft-start (ramp-up), gradually increasing acoustic energy from low to full operational power over 20–30 minutes, in accordance with the Marine Mammal Mitigation Plan. If a marine mammal or sea turtle is detected within the 500 m zone before full power is reached, acoustic operations shall be suspended and shall not recommence until the applicable clearance, and restart requirements have been met.                                                                                                                                                                                                                                                                                             |
|                                             |                                                                                   | <b>MM2-108</b> If marine mammals or sea turtles are detected within the 500 m mitigation zone, acoustic operations shall be delayed until the animals have left the area and at least 20 minutes have elapsed since the last visual sighting, or for any longer period specified in the Marine Mammal Mitigation Plan.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                             |                                                                                   | <b>MM2-109</b> In the event of a collision between a Project vessel and a marine mammal or sea turtle, the vessel's Master shall immediately report the incident to Energean in accordance with the Project's incident-reporting procedure. Energean shall, as soon as reasonably practicable and within any applicable regulatory timeframe, formally notify the competent environmental and other relevant authorities, as required by applicable legislation.                                                                                                                                                                                                                                                                                                            |
|                                             |                                                                                   | <b>MM2-110</b> Project-related vessels shall operate at speeds not exceeding 14 knots, or their maximum operational speed where lower, within areas identified in the Marine Mammal Mitigation Plan as having higher marine mammal presence, without compromising vessel safety or emergency response capability.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                             |                                                                                   | <b>MM2-111</b> Vessels shall maintain a safe distance from any observed marine mammal, avoid approaching it head-on, avoid crossing or waiting ahead of its direction of travel, and, where safe and practicable, steer behind its path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                             |                                                                                   | <b>MM2-112</b> No planned discharge from the MODU or Project vessels shall be made if at any point a vessel is within the Ionian Archipelago IMMA or the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi (GR2230003) Natura 2000 site.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE              | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                   | <b>MM2-113</b> Appropriate screens or equivalent protective measures shall be fitted to the drillship seawater intakes to minimise the risk of entrainment of marine flora and fauna.                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                          |                                   | <b>MM2-114</b> Light emissions shall be minimised during night-time hours, as far as practicable while maintaining safe operations and navigational requirements. Directional lighting shall be used, where practicable, to minimise light spill onto the sea.                                                                                                                                                                                                                                                                                                                                          |
|                          |                                   | <b>MM2-115</b> External lighting shall comply with applicable maritime, aviation, Flag State and operational safety requirements. Where practicable without affecting those requirements, non-essential lighting shall be positioned, directed or shielded to minimise unnecessary upward and outward light spill, particularly during bird-migration periods.                                                                                                                                                                                                                                          |
|                          |                                   | <b>MM2-116</b> Where fitted, blinds or other available screening shall be used on accommodation windows during hours of darkness, where practicable, to minimise unnecessary outward light spill, particularly during bird-migration periods.                                                                                                                                                                                                                                                                                                                                                           |
|                          |                                   | <b>MM2-117</b> Helicopter flights shall be planned and conducted by the helicopter operator in accordance with applicable aviation requirements, air-traffic-control instructions and Corfu International Airport operator procedures. Where safe and operationally practicable, flight routes and altitudes shall be selected to avoid unnecessary overflight of known bird breeding, roosting or concentration areas identified as relevant to the Project.                                                                                                                                           |
| Maritime uses            | Minimise impacts on maritime uses | <b>MM2-118</b> The OIM/Master of the MODU and the Master of each support vessel shall have overriding authority and responsibility to make decisions with respect to safety and pollution prevention, in accordance with the ISM Code. The MODU and Project support vessels will comply with applicable international and national maritime legal requirements, including COLREGs (Ref. ii) and the display of appropriate lights, shapes and signals.                                                                                                                                                  |
|                          |                                   | <b>MM2-119</b> The main operators of cruise ships and LNG carriers identified through the Shipping and Navigation Assessment as regularly passing within or near 500 m of the site shall be provided with advance notice of the Asopus-1 operations. This notice shall supplement applicable official navigational notifications, including NAVTEX messages and Notices to Mariners, enabling the vessel operators to review or amend their passage plans, if required.                                                                                                                                 |
|                          |                                   | <b>MM2-120</b> The MODU will have a vessel-specific collision risk management plan, informed by the site-specific Shipping and Navigation Assessment, to reduce the risk of collision from third-party vessels while it is restricted in its ability to manoeuvre (RAM) and engaged in well operations. The plan shall include measures to provide adequate warning time, continuous monitoring of marine traffic by competent watchkeepers using AIS, ARPA and other available navigational aids, and appropriate communications, lights, shapes and signals reflecting the MODU's operational status. |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                                                                            | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|-------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          |                                                                                                 | <p><b>MM2-121</b> Project support vessels shall be scheduled and operationally coordinated by the Project logistics team. The owners and/or operators of the Platform Supply Vessels shall be responsible for ensuring that each vessel displays the applicable lights and marks and operates AIS, where required, and complies with applicable international, Flag-State, and coastal-State requirements, including applicable Greek legislation, COLREGs (Ref. ii) and SOLAS (Ref. x).</p>                                                                              |
|                          |                                                                                                 | <p><b>MM2-122</b> Subject to authorisation by the competent Greek authorities, a 500 m safety zone around the MODU will be established and notified for the duration of well operations. Unauthorised vessel access to the safety zone will be restricted in accordance with the applicable authorisation and maritime notices. The PSVs will assist the MODU in monitoring the safety zone and communicating with approaching vessels, as required, whilst on site.</p>                                                                                                  |
|                          |                                                                                                 | <p><b>MM2-123</b> Information on the establishment and duration of the safety zone, and relevant details of the operation, shall be disseminated through official maritime-safety information channels, including NAVTEX messages, navigational warnings, and, where applicable, Notices to Mariners, issued or coordinated by the Hellenic Navy Hydrographic Service in cooperation with the competent Hellenic Coast Guard authorities.</p>                                                                                                                             |
|                          |                                                                                                 | <p><b>MM2-124</b> The drillship will have an Emergency Response Plan detailing procedures to be followed in an emergency. The MODU shall also maintain Well-Specific Operating Guidelines (WSOG), informed by the applicable station-keeping, riser and emergency-disconnect analyses, defining the operating limits, alert status and actions for loss or degradation of position. Where required by the WSOG and associated MODU procedures, the Emergency Disconnect Sequence (EDS) shall be initiated to secure the well and enable the MODU to disengage safely.</p> |
|                          |                                                                                                 | <p><b>MM2-125</b> The Operator will maintain appropriate liaison with relevant fishing associations during drilling operations to communicate material changes or issues that may affect fishing activities and, where reasonably practicable, minimise interference with fishing vessels.</p>                                                                                                                                                                                                                                                                            |
| Cultural heritage        | Protect underwater cultural heritage and ensure appropriate management of chance archaeological | <p><b>MM2-126</b> During drilling operations, personnel engaged in seabed interaction or subsea observation shall remain aware of the applicable cultural heritage controls. If suspected archaeological material is identified, any activity under their control that could disturb the suspected find shall be stopped, and the discovery shall be promptly reported and managed in accordance with the Project Chance Find Procedure.</p>                                                                                                                              |

| ENVIRONMENTAL PARAMETERS | OBJECTIVE OF MEASURE                    | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | discoveries                             | <p><b>MM2-127</b> No archaeological remains were identified within the immediate project footprint. However, should material of possible archaeological significance be encountered during project activities, the following Chance Find Procedure shall be implemented: • The affected activity shall be stopped to the extent necessary to avoid disturbance. • Record the location and nature of the find and apply practicable controls to avoid further disturbance. • Obtain photographic and/or video documentation of the discovery where practicable. • Inform the OIM/Master and the designated Project representative through the defined Project reporting route. • Obtain advice from an appropriately qualified maritime archaeologist where required to support notification, preliminary interpretation or the response requested by the competent authority. • The designated Project representative shall notify the Ephorate of Underwater Antiquities within the timeframe required by applicable law, permit conditions or agreed notification arrangements, providing the available relevant information. • The suspended seabed-disturbing activity shall not recommence within the affected area until authorised by the Project Operator, taking into account the OIM/Master's independent authority and any direction received from the competent authority.</p> |
|                          |                                         | <p><b>MM2-128</b> The Cultural Heritage Management Plan should be reviewed and updated where necessary if: • New archaeological discoveries are made; • Additional geophysical or seabed investigations provide new, material information relevant to the cultural heritage assessment or the planned disturbance footprint; • Project activities are modified in a manner that may affect cultural heritage resources; • New information becomes available regarding the archaeological potential of the project area.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Economic Activities      | Minimise impacts on economic activities | <p><b>MM2-129</b> The Project shall actively identify and engage with capable local and other Greek suppliers and service providers for logistics, port services, and other support activities where they meet the Project's safety, operational, and commercial requirements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          |                                         | <p><b>MM2-130</b> Regular and timely communication shall be maintained with the Hellenic Coast Guard, relevant fisheries organisations, the Port Authorities of Igoumenitsa and Corfu, Corfu International Airport operator, and other identified key stakeholders throughout operations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Personnel shall receive project-specific briefings on marine operations, traffic management and emergency response, as applicable. Lifting operations shall be carried out by the appropriate contractor with the required competence and qualifications. |
|                          |                                                                                           | <b>MM2-136</b> Emergency response drills, including fire, medical evacuation, man overboard and oil spill response exercises, shall be conducted at intervals defined in the Project and vessel emergency response procedures, and in accordance with applicable legal and Flag-State requirements.                                                                                                                                                                                                                                |
|                          |                                                                                           | <b>MM2-137</b> Subject to authorisation by the competent Greek authorities, the 500 m safety zone around the MODU shall be maintained during well operations and notified through applicable official maritime-safety information channels. The MODU shall maintain continuous watchkeeping using AIS, ARPA, VHF and other available navigational aids, consistent with the Shipping and Navigation Assessment.                                                                                                                    |
|                          |                                                                                           | <b>MM2-138</b> Sealed radioactive sources may be used only where required for formation-evaluation tools within specific well-logging or logging-while-drilling tools. Their use, storage and transport shall be managed by the relevant licensed contractor in accordance with applicable EEAE authorisations, Greek radiation-protection requirements and the contractor's approved radiation-safety procedures.                                                                                                                 |
|                          |                                                                                           | <b>MM2-139</b> Chemical handling shall follow the Chemical Use Plan and applicable contractor procedures, including review of relevant Safety Data Sheets, appropriate containment and segregation, and spill-prevention and response arrangements at the shore base and offshore.                                                                                                                                                                                                                                                 |
|                          |                                                                                           | <b>MM2-140</b> Helicopter transfers between Corfu International Airport and the MODU shall be conducted by the helicopter operator in accordance with applicable aviation requirements and the requirements and procedures of the Corfu International Airport operator, taking account of operational, air traffic and weather conditions, to minimise risks to third parties.                                                                                                                                                     |
| Technical Infrastructure | Avoid disruption to maritime, energy, telecommunications and environmental infrastructure | <b>MM2-141</b> Project activities at the Port of Igoumenitsa shall be undertaken in accordance with the applicable Environmental Terms (Ref. No. 139663103448/08/01.06.2009, as amended and in effect at the time of this assessment).                                                                                                                                                                                                                                                                                             |

| ENVIRONMENTAL PARAMETERS                | OBJECTIVE OF MEASURE                                                    | MITIGATION MEASURES DURING DRILLING OPERATIONS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Environmental Management and Monitoring | Ensure environmental compliance and verification of mitigation measures | <b>MM2-142</b> An Environmental Monitoring Programme (EMP) shall be implemented throughout the Project to verify compliance with applicable environmental requirements and monitor the effectiveness of mitigation measures. Monitoring shall include, as appropriate, drilling discharges, seawater quality, waste management, chemical use, environmental incidents and marine fauna observations. Monitoring results shall be reviewed in accordance with the EMP, and proportionate corrective actions implemented where necessary. |

### 11.2.3 Proposed measures during decommissioning phase – site restoration

The mitigation measures (MM3) for the prevention, minimisation and management of potential environmental and social impacts during the decommissioning and site restoration phase are presented in Table 11-3.

The following general principles shall apply during the decommissioning and site restoration phase:

- The exploration well shall be plugged and abandoned in accordance with the accepted Notification of Well Operations (NoWO), applicable regulatory requirements, the approved P&A programme and Good International Industry Practice, to provide long-term well integrity and prevent unintended releases to the marine environment.
- Temporary subsea equipment deployed by the Project during the drilling campaign, including the marine riser, blowout preventer and acoustic positioning transponders, shall be recovered following completion of well operations.
- Following P&A and recovery of the temporary subsea equipment, an ROV seabed survey shall be undertaken within a 50 m radius of the well location to identify Project-related debris. Any Project-related debris identified shall be documented and managed in accordance with applicable operational and regulatory requirements.
- As the MODU will use dynamic positioning for routine station-keeping, no anchoring is planned and no anchor-recovery or associated seabed-restoration activities are anticipated.
- Project equipment, materials, chemicals and wastes remaining on the MODU and at the onshore support facilities following completion of Project use shall be removed or otherwise managed in accordance with the Project Waste Management Plan, applicable legislation and arrangements agreed with the relevant facility operator. Materials shall be reused or recycled where reasonably practicable, and wastes shall be transferred to authorised waste-management facilities.
- Temporary Project facilities, equipment, signage and operational arrangements at the Port of Igoumenitsa and Corfu International Airport shall be removed, retained or otherwise managed in accordance with arrangements agreed with the relevant facility operator. Areas used by the Project shall be left in the condition agreed with the relevant facility operator.
- Records relating to P&A, recovery of temporary subsea equipment, waste transfers and post-operation inspections shall be maintained and submitted to the competent authorities where required by applicable regulatory requirements.

**Table 11-3: Mitigation measures for potential adverse environmental and social impacts during the decommissioning and site restoration phase of the project**

| ENVIRONMENTAL PARAMETERS                                 | OBJECTIVE OF MEASURE                                                                       | MITIGATION MEASURES DURING DECOMMISSIONING & SITE RESTORATION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Climatic and Bioclimatic Characteristics                 | Minimise greenhouse gas emissions and atmospheric pollutants                               | <b>MM3-32</b> Each Project Contractor shall maintain all machinery, vessels, and vehicles used in the Project according to manufacturer specifications to reduce exhaust emissions. Maintenance shall be carried out by the relevant contractor/owner in accordance with manufacturer schedules, at licensed onshore facilities where practicable.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                                          |                                                                                            | <b>MM3-33</b> The MODU and all support vessels shall comply with the requirements of MARPOL 73/78 Convention, Annex VI "Regulations for the Prevention of Air Pollution from Ships". Annex VI regulates emissions of ozone-depleting compounds, nitrogen oxides (NOx), sulfur oxides (SOx) and volatile organic compounds (VOCs).                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                          |                                                                                            | <b>MM3-34</b> Energean shall coordinate with relevant Contractors, the Port Authority and Corfu International Airport to optimise support vessel and helicopter logistics through careful voyage planning, taking into account rig operational requirements, so as to minimise the number of vessel trips, reduce the duration of activities within the project area, and avoid unnecessary engine operation and idling, to the extent achievable within the operational constraints of each party involved.                                                                                                                                                                                                                                                                            |
| Morphological and Landscape Characteristics              | Restore the project area and prevent permanent alteration of seabed and onshore facilities | <b>MM3-35</b> Upon completion of drilling and Plug and Abandonment (P&A), temporary subsea equipment deployed by the Project shall be recovered. An ROV seabed survey shall be undertaken within a 50 m radius of the well location to identify Project-related debris. Temporary Project equipment and materials shall be removed from the onshore support facilities or otherwise managed in accordance with arrangements agreed with the relevant facility operator.                                                                                                                                                                                                                                                                                                                 |
|                                                          |                                                                                            | <b>MM3-36</b> Any temporary areas used for Project activities at the onshore logistics base shall be left in the condition agreed with the relevant facility operator following completion of Project use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Geological, Tectonic and Soil / Sediment Characteristics | Protect soil / sediment and minimise physical and chemical disturbance                     | <b>MM3-37</b> Hazardous and non-hazardous wastes (identified as such under applicable legislation or the relevant Safety Data Sheet) generated offshore shall be segregated, stored, handled and transferred to authorised shore reception or waste-management facilities in accordance with the Project Waste Management Plan and the applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. No solid or hazardous waste shall be intentionally discharged to the marine environment. Operational discharges, including drilling fluids and cuttings, sewage, bilge water, ballast water and food waste, shall be managed in accordance with the relevant discharge-specific measures and applicable legal requirements. |
|                                                          |                                                                                            | <b>MM3-38</b> The exploration well shall be plugged and abandoned in accordance with the accepted HEREMA Notification of Well Operations (NoWO), applicable regulatory requirements, the approved P&A programme, and Good International Industry Practice (GIIP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                          |                                                                                            | <b>MM3-39</b> Permanent cement barriers shall be installed and verified using methods appropriate to the barrier type and well conditions, in accordance with the accepted NoWO, approved well programme, applicable regulatory requirements and Good International Industry Practice.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Seawater                                    | Protect seawater quality                                                                                    | <b>MM3-43</b> Offshore-generated hazardous and non-hazardous wastes shall be managed in accordance with the Waste Management Plan and applicable requirements of MARPOL, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation. Operational discharges shall be managed in accordance with the requirements applicable to each discharge stream, including MARPOL, the BWM Convention, the Barcelona Convention and its Offshore Protocol, and EU and Greek legislation, as relevant. Chemical selection, use and discharge shall be controlled through the Chemical Use Plan.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Flora, fauna, habitats, and protected areas | Protect marine fauna and verify restoration of the seabed                                                   | <p><b>MM3-44</b> Project-related vessels shall operate at speeds not exceeding 14 knots, or their maximum operational speed where lower, within areas identified in the Marine Mammal Mitigation Plan as having higher marine mammal presence, without compromising vessel safety or emergency response capability.</p> <p><b>MM3-45</b> Vessels shall maintain a safe distance from any observed marine mammal, avoid approaching it head-on, avoid crossing or waiting ahead of its direction of travel, and, where safe and practicable, steer behind its path.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Maritime uses                               | Minimise impacts on maritime uses                                                                           | <p><b>MM3-46</b> The Operator will maintain appropriate liaison with relevant fishing associations during well decommissioning to communicate material changes or issues that may affect fishing activities and, where reasonably practicable, minimise interference with fishing vessels.</p> <p><b>MM3-47</b> The main operators of cruise ships and LNG carriers identified through the Shipping and Navigation Assessment as regularly passing within or near 500 m of the site shall be provided with advance notice of the Asopus-1 operations. This notice shall supplement applicable official navigational notifications, including NAVTEX messages and Notices to Mariners, enabling the vessel operators to review or amend their passage plans, if required.</p> <p><b>MM3-48</b> The OIM/Master of the MODU and the Master of each support vessel shall have overriding authority and responsibility to make decisions with respect to safety and pollution prevention, in accordance with the ISM Code. The MODU and Project support vessels will comply with applicable international and national maritime legal requirements, including COLREGs (Ref. ii) and the display of appropriate lights, shapes and signals.</p> <p><b>MM3-49</b> Project support vessels shall be scheduled and operationally coordinated by the Project logistics team. The owners and/or operators of the Platform Supply Vessels shall be responsible for ensuring that each vessel displays the applicable lights and marks and operates AIS, where required, and complies with applicable international, Flag-State, and coastal-State requirements, including applicable Greek legislation, COLREGs (Ref. ii) and SOLAS (Ref. x).</p> <p><b>MM3-50</b> Subject to authorisation by the competent Greek authorities, a 500 m safety zone around the MODU will be established and notified for the duration of well operations. Unauthorised vessel access to the safety zone will be restricted in accordance with the applicable authorisation and maritime notices. The PSVs will assist the MODU in monitoring the safety zone and communicating with approaching vessels, as required, whilst on site.</p> <p><b>MM3-51</b> Information on the establishment and duration of the safety zone, and relevant details of the operation, shall be disseminated through official maritime-safety information channels, including NAVTEX messages, navigational warnings, and, where applicable, Notices to Mariners, issued or coordinated by the Hellenic Navy Hydrographic Service in cooperation with the competent Hellenic Coast Guard authorities.</p> |
| Cultural Heritage                           | Protect underwater cultural heritage and ensure appropriate management of chance archaeological discoveries | <p><b>MM3-52</b> No archaeological remains were identified within the immediate project footprint. However, should material of possible archaeological significance be encountered during project activities, the Chance Find Procedure shall be implemented.</p> <p><b>MM3-53</b> Any discoveries of potential archaeological significance shall be documented in accordance with the Chance Find Procedure and reported to the competent cultural heritage authorities. Consultation with the Ephorate of Underwater Antiquities shall be undertaken as required regarding any further assessment or protective measures.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Economic Activities                         | Minimise impacts on economic activities                                                                     | <b>MM3-54</b> The Project shall actively identify and engage with capable local and other Greek suppliers and service providers for logistics, port services, and other support activities where they meet the Project's safety, operational, and commercial requirements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Lifting operations shall be carried out by the appropriate contractor with the required competence and qualifications.</p> <p><b>MM3-59</b> Emergency response drills, including fire, medical evacuation, man overboard and oil spill response exercises, shall be conducted at intervals defined in the Project and vessel emergency response procedures, and in accordance with applicable legal and Flag-State requirements.</p> <p><b>MM3-60</b> Waste contractor collections and any removal or dismantling of temporary Project facilities and equipment shall be scheduled and coordinated with the relevant port and airport facility operators to minimise disruption and risks to other facility users.</p> |
| Technical Infrastructure                | Avoid disruption to existing infrastructure and navigation routes during project activities | <p><b>MM3-61</b> Decommissioning and demobilisation activities shall be planned and coordinated with the relevant port and airport facility operators. Activity timing and arrangements shall, where reasonably practicable, be adjusted to minimise disruption to other facility users, without compromising safety, emergency-response, asset integrity or operational requirements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Environmental Management and Monitoring | Ensure environmental compliance and verification of mitigation measures                     | <p><b>MM3-62</b> An Environmental Monitoring Programme (EMP) shall be implemented throughout the Project to verify compliance with applicable environmental requirements and the effectiveness of mitigation measures. Monitoring shall include, as appropriate, drilling discharges, seawater quality, waste management, chemical use, environmental incidents and marine fauna observations. Monitoring results shall be reviewed in accordance with the EMP, and proportionate corrective actions shall be implemented where necessary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 11.3 Proposed measures for non-routine operations

### 11.3.1 Contingency activities triggered by unfavourable operational circumstances

If technical or operational issues arise during drilling, contingency activities may be required to prevent operational failures from resulting in the permanent loss or abandonment of the exploration well and its objectives, thereby preserving the opportunity to reach the target reservoir despite unforeseen drilling problems. More specifically, they help prevent:

- Loss of the well due to mechanical or geological problems

- Abandonment of the well before reaching the target reservoir
- Loss of the wellbore because of stuck pipe, collapse or directional issues
- Excessive delays and cost overruns by providing predefined recovery options
- Safety and environmental incidents by enabling controlled responses to well integrity or pressure issues

Contingency activities are not part of the planned base case of the Project but may be undertaken in response to unforeseen operational circumstances. If undertaken, they may increase operational duration, drilling-fluid and cement use, cuttings and drilling-fluid discharges, and localised seabed disturbance compared with the planned well programme.

**Table 11-4: Contingency activities and measures**

| HAZARDS                                                | CONTINGENCY MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inability to continue the original wellbore            | Re-spudding may be necessary if issues arise that make it impractical to continue drilling the current well. Additional cuttings and drilling-fluid discharges may be generated, and additional cement may be required, depending on the stage at which the re-spud is undertaken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Inability to continue the existing wellbore trajectory | A sidetrack may be required where technical, geological or wellbore conditions make it impractical to continue along the existing wellbore trajectory. The relevant section of the original wellbore shall be isolated, where required, using an appropriate barrier or mechanical system in accordance with the approved well programme and applicable well-integrity requirements. Any sidetrack shall be subject to the applicable management-of-change procedures and any regulatory notification, acceptance or environmental-permitting requirements arising from the proposed change. Any re-spud shall be managed within the assessed Project design envelope or through the applicable management-of-change and regulatory processes.                                        |
| Loss or degradation of MODU station-keeping            | Temporary interruption of operations may be required during the drilling campaign due to adverse weather, equipment issues, or other operational circumstances. Where disconnection from the well is required, the well will be secured using the applicable well barriers and disconnect procedures before the MODU moves off location. Operations may resume once conditions allow and the applicable operational and regulatory requirements have been satisfied.                                                                                                                                                                                                                                                                                                                  |
| Emergency disconnection from the well                  | A contingent Emergency Disconnect Sequence (EDS) may be initiated in the unlikely event the MODU needs to rapidly disengage from the well (e.g., due to severe weather). The EDS is designed to secure the well through the applicable BOP functions before disconnection of the lower marine riser package. Activation may result in the release of a limited quantity of riser contents, including drilling fluid and entrained cuttings, to the marine environment.                                                                                                                                                                                                                                                                                                                |
| Well influx / kick                                     | Managed in accordance with the project well-control bridging document. Response actions may include shutting in the well, monitoring well pressures, and circulating the influx from the wellbore while maintaining control with the applicable well-control equipment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Well Barrier failure / degradation                     | Well-barrier failure or degradation shall be managed in accordance with the Project Well Control Bridging Document and applicable well-integrity procedures. The well shall be placed in a safe condition, and remedial operations shall be undertaken as required to restore or replace the affected barrier before dependent operations resume.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Stuck pipe requiring mechanical severance              | Explosives or other cutting tools may be maintained onboard in limited quantities as a contingency measure for mechanical pipe severance (for example in stuck-pipe scenarios). No Tubing-Conveyed Perforating (TCP) or other reservoir-targeting explosive operations are planned for the Asopus-1 campaign. The types and quantities of cutting tools held onboard, and their storage, handling, and use, will be controlled in accordance with applicable legal requirements, vessel procedures, and specialist-vendor arrangements. Tool components and severed tubulars will be recovered where safe and operationally practicable. Any material that cannot be recovered shall be documented and managed in accordance with applicable operational and regulatory requirements. |

## 11.3.2 Proposed major accident prevention and response measures

### 11.3.2.1 Preventive and protective measures

The Project has incorporated a range of preventive and protective measures to reduce the likelihood and potential impacts of major accident hazards associated with offshore drilling activities. These measures include engineering controls, operational procedures, equipment integrity management, inspection and maintenance programmes, monitoring systems, and personnel training. Together, they help prevent major accident hazards and minimise potential impacts on personnel, the marine environment and project assets, ensuring that residual risks are reduced to a level that is As Low As Reasonably Practicable (ALARP). Table 11-5 presents the proposed major accident / hazards prevention measures.

**Table 11-5: Proposed major accident / hazards prevention measures**

| HAZARD                               | MAJOR ACCIDENT / HAZARDS PREVENTION MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Blowout and Well Releases            | <ul style="list-style-type: none"> <li>Well control shall be managed through primary, secondary and, where required, tertiary well-control measures in accordance with the approved well programme, the Project Well Control Bridging Document and applicable well-control procedures. Primary well control shall be maintained using the drilling-fluid system and, where applicable, other approved pressure-control techniques. Secondary well control shall use the BOP and associated equipment to shut in and control the well following a loss of primary well control. Where primary and secondary measures are insufficient, appropriate tertiary well-control techniques shall be selected and implemented according to the circumstances.</li> <li>A pre-positioned Emergency Shut-In Device (E-SID), installed between the wellhead and the MODU BOP, will provide an additional independent emergency well-isolation capability. The device can shear and seal on any tubular or cable that may be run inside the well. In the unlikely scenario that the BOP stack fails to shut in a well if required, the E-SID will be activated, and the well will be secured.</li> </ul> <p>The selected MODU shall be equipped with well-control, monitoring, detection, shutdown and emergency systems appropriate to the well and operational hazards and compliant with applicable Flag State, classification, regulatory and Project assurance requirements. Rig-specific arrangements shall be verified through MODU selection, well examination, contractor assurance and the Notification of Well Operations.</p> <p>Source-control arrangements proportionate to the assessed well-release scenarios shall be established for the campaign. These shall address, as applicable, BOP intervention, subsea capping, containment (if applicable) and relief-well planning, in accordance with the Project emergency-response arrangements and applicable regulatory requirements.</p> |
| Fires, Explosions and Toxic Releases | <p>Mud process areas (shale-shaker, mud pits and mud pump rooms) are designated as Zone 1 (a zone in which an explosive atmosphere is likely to occur during normal operation) hazardous areas and shall be protected by mechanically forced negative-pressure ventilation.</p> <p>Flammable gas detectors shall be installed to detect the presence of flammable gas. Low-expansion foam shall be provided for firefighting in the mud process area, and an A60-rated fire wall shall be provided around the boundaries of the shaker room.</p> <p>The shaker-room entrance door shall be located in an unclassified area (cement unit), while CCTV shall be installed in the shale shaker room to facilitate monitoring of the shaker room.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| HAZARD                      | MAJOR ACCIDENT / HAZARDS PREVENTION MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <p>The main engine rooms shall be protected by gas, smoke and flame detection, a fire alarm push-button, a fixed CO<sub>2</sub> extinguishing system, portable firefighting equipment and fire hose stations.</p> <p>The bulkheads separating the engine rooms shall be A-60-rated. Fuel-oil cut-off valves shall be available and shall be remotely operated from outside the main engine room.</p> <p>Two detectors shall be provided at each air intake. The engine room ventilation shall shut down automatically when gas is detected in the engine room air intake. Protection against gas ingress through the combustion air shall be provided by rig savers.</p> <p>The vessel shall be equipped with enclosed escape tunnels on the port and starboard sides leading from aft to the accommodation block.</p> <p>HVAC systems comprising supply and exhaust dampers shall be installed at the aft and forward port and starboard positions of the escape tunnels to provide the needed pressurisation to prevent the ingress of smoke and gas into the tunnels.</p> <p>An extra door shall be provided to the escape tunnel to facilitate escape from the drill floor and minimise exposure of people in this area to hazardous events. Watertight doors in the escape tunnels shall be kept open unless a visiting vessel is approaching.</p> <p>The helideck refuelling tank is now located on deck 10 behind a firewall. The area is protected by a deluge system which can be operated remotely. In addition, the Heli guard station has been equipped with CCTV for improved fire monitoring. This use of the helideck refuelling tank is not planned for the campaign.</p> <p>H<sub>2</sub>S detectors shall be in the areas where gas is most likely to be released. Detection of toxic gas (10 ppm) shall give an alarm. High toxic gas (20 ppm) shall initiate the relevant emergency shutdown actions, including automatic control of the ventilation system in the related area.</p> <p>Where drilling into a potentially sour reservoir is anticipated, appropriate additional measures to manage the H<sub>2</sub>S hazard shall be put in place.</p> <p>The storage and use of hazardous or potentially toxic materials kept onboard shall be strictly controlled by MODU procedures. Small toxic gas releases resulting from normal or primary well control operations or from core breakout shall be controlled by standard contingency procedures.</p> <p>The drillship Emergency Response Plan shall define alarm, shutdown, firefighting, muster, evacuation, escape and rescue arrangements for fire, explosion and toxic-release events.</p> |
| Ship Collision              | <p>Despite the 500-metres restricted area, the MODU shall have a vessel-specific collision risk management plan, informed by the site-specific Shipping and Navigation Assessment. The plan shall include measures to provide adequate warning time, continuous monitoring of marine traffic by competent watchkeepers using AIS, ARPA and other available navigational aids, and appropriate communications, lights, shapes and signals reflecting the MODU's operational status.</p> <p>Radio communications, light signals and sound signals shall be used by the MODU and available support or standby vessels to warn vessels presenting a collision threat.</p> <p>The MODU and Platform Supply Vessels shall comply with COLREGs, SOLAS, applicable Flag State requirements and relevant national requirements, including display of the appropriate navigation lights, marks and day shapes for a vessel Restricted in its Ability to Manoeuvre.</p> <p>Subject to authorisation by the competent Greek authorities, a 500 m safety zone shall be maintained around the MODU during well operations. Project support vessels shall assist in monitoring the zone and communicating with approaching vessels, as required.</p> <p>Where an imminent collision threat cannot be managed through warning or vessel-intervention measures, the applicable emergency response, DP and disconnect procedures shall be implemented in accordance with the WSOG and MODU procedures.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Loss of Dynamic Positioning | <p>The MODU's dynamic-positioning system shall meet IMO DP Equipment Class 3 requirements or an equivalent Class 3 notation accepted by the relevant Flag State and classification society. Loss or degradation of station-keeping shall be managed in accordance with the WSOG and applicable MODU procedures, including emergency disconnection and movement off location where required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Dropped Objects             | <p>Critical areas, including the Temporary Refuge, control rooms, switch rooms and fuel-oil tanks, shall be protected against dropped-object impacts by plated structural decks. Lifting procedures shall prohibit lifting heavy loads directly over live hydrocarbon-containing equipment.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Extreme Weather             | <p>The MODU shall be operated within the designed environmental limits.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Helicopter Accidents        | <p>The helideck shall be designed, certified, operated and maintained in accordance with applicable Flag State, classification, aviation and helicopter-operator requirements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| HAZARD | MAJOR ACCIDENT / HAZARDS PREVENTION MEASURES                                                                                                                                                                                                                                    |

|        | The helideck refuelling tank shall be located behind a firewall and the area is protected by a remotely operated deluge system. Additionally, the Heli guard station is equipped with CCTV for improved fire monitoring to reduce the likelihood of a helideck fire escalating. |

### 11.3.2.2 Emergency response measures

In addition to the preventive measures described above, comprehensive emergency response measures have been established to ensure that emergency events will be managed promptly, safely and effectively. These measures include clearly defined roles and responsibilities, incident management procedures, communication and notification protocols, emergency response resources, evacuation and rescue procedures, and regular training and exercises. Together, they are intended to protect personnel, minimise environmental impacts, maintain effective command and control, and support the safe recovery of operations following an incident.

Response to oil pollution incidents will be undertaken in accordance with the applicable vessel Shipboard Oil Pollution Emergency Plan (SOPEP). Accidental releases of other chemicals will be managed through the relevant vessel and Project emergency procedures, taking account of the substance involved, its Safety Data Sheet and the nature and scale of the release. These arrangements will be implemented in accordance with applicable international, EU, Greek, flag-State, and port-State requirements and will be supported by the relevant drills and exercises.

Table 11-6 presents the proposed emergency response measures.

**Table 11-6: Proposed emergency response measures**

| EMERGENCY CATEGORY                    | EMERGENCY RESPONSE MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Immediate Actions and General Command | <p>The emergency response shall be managed in the following strict priority order: (1) Protect life, (2) Stabilise and regain control, (3) Protect the environment, (4) Protect the asset, and (5) Preserve evidence.</p> <p>The Bronze Leader (on-scene command role defined by the ERP) shall assume on-scene tactical command, stop affected work, isolate energy and ignition sources, establish exclusion zones, and coordinate the initial emergency response. Emergency alarms shall be activated, personnel shall be accounted for at muster stations, and procedures for partial evacuation, full evacuation or abandonment shall be initiated where required.</p>                                                              |
| Blowout and Well Control              | <p>In the unlikely event of a blowout or other loss of well control, drilling operations shall be suspended, and the well shall be secured using the applicable well-control equipment and procedures. Well pressure, flow and barrier status shall be monitored and appropriate well-control actions implemented in accordance with the Project Well Control Bridging Document. The BOP, E-SID, ESD, EDS and applicable DP response procedures shall be activated where required by the circumstances and relevant operating procedures. Where control cannot be restored using available well-control measures, the applicable source-control arrangements, including subsea capping and relief-well planning, shall be initiated.</p> |
| Fire and Explosion                    | <p>In the event of a fire or explosion, trained emergency response teams shall deploy the applicable fixed firefighting systems, isolate fuel and ignition sources, undertake boundary cooling, and control smoke to protect escape routes, as appropriate to the circumstances. Ventilation shall be managed, access to affected areas shall be restricted, and breathing apparatus shall be used where necessary to protect emergency responders.</p>                                                                                                                                                                                                                                                                                  |

| EMERGENCY CATEGORY                                 | EMERGENCY RESPONSE MEASURES                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Marine Emergencies and Man Overboard               | Dynamic Positioning drive-off or drift-off events shall be managed in accordance with the Well-Specific Operating Guidelines and applicable MODU procedures, including emergency disconnection where required. Following collision or structural damage, flooding control, stability assessment and pollution containment measures shall be initiated as appropriate to the nature of the event. During man-overboard incidents, rescue equipment shall be deployed immediately, visual contact shall be maintained where practicable, and available support vessels and, where required, the competent search-and-rescue authorities shall be coordinated in accordance with the applicable emergency procedures.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Medical Emergencies and Medevac                    | An injured person (IP) shall be assessed and stabilised onboard by the Rig Medic with support from topside medical advisers where required. Medical evacuation shall be undertaken by helicopter or vessel, depending on the IP condition and prevailing operational conditions, to a suitable receiving medical facility. For multiple casualties or complex rescue operations, assistance shall be requested from and coordinated through the Joint Rescue Coordination Centre and the Hellenic Coast Guard, as required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Toxic Gas (Hydrogen Sulphide) Releases             | In the unlikely event of a toxic-gas release, personnel shall be relocated to designated safe areas upwind, crosswind or within protected spaces. Heating, Ventilation and Air Conditioning (HVAC) controls shall be used to limit gas ingress, while escape sets, breathing apparatus and exclusion zones shall be implemented as required to protect personnel. Where required by the nature and scale of the release, external plume-dispersion modelling may be undertaken to assess potential offsite impacts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Spill and Pollution Response                       | <p>The source of the spill shall be controlled where safe and practicable, and the activity associated with the loss of containment shall be suspended or isolated, as appropriate. Initial containment, recovery and protection measures shall be selected and deployed taking account of the substance released, the location and scale of the spill, prevailing conditions and available response capability. The response shall be escalated according to the nature and scale of the incident, with additional personnel, equipment and specialist response resources mobilised where required under the applicable vessel and Project spill-response arrangements.</p> <p>Where the spill exceeds onsite response capability, the competent authorities shall be notified, and additional response resources shall be mobilised in accordance with the applicable spill-response arrangements. The detailed response arrangements, including response organisation, notification, escalation, available resources and coordination with contractors and competent authorities, shall be defined in the applicable emergency and spill-response plans. Any activation of the National Contingency Plan shall be determined by the competent authorities. Chemical dispersants shall only be used following approval by the competent authority. Spill monitoring, waste management and environmental surveillance shall continue as appropriate to the nature and scale of the incident until response and recovery operations are completed.</p> <p>Response to oil pollution incidents will be undertaken in accordance with the applicable vessel Shipboard Oil Pollution Emergency Plan (SOPEP) and Project Emergency Response Plan which spill-response arrangements are included. Releases involving other chemicals will be managed through the relevant vessel and Project emergency procedures, taking account of the substance involved, its Safety Data Sheet and the nature and scale of the release.</p> |
| Special Hazards (Security, Cyber and Radiological) | <p>Security and cyber incidents shall be managed in accordance with applicable MODU, contractor and Project procedures, including, as appropriate, access control, isolation of affected Information Technology (IT) and Operational Technology (OT) systems, and implementation of manual operating procedures where safe.</p> <p>For radiological incidents, affected work shall be stopped, the affected area shall be isolated, access shall be controlled, and suitably qualified radiation-protection personnel shall be consulted or mobilised in accordance with the relevant licensed contractor's approved procedures and applicable EEAE requirements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 11.3.3 Proposed measures to enhance climate change adaptation

The climate vulnerability assessment presented in Chapter 10 identified flooding and changes in wind characteristics as the only climate-related hazards requiring additional adaptation measures, based on their

Medium or High inherent risk. Hazards assessed as Low risk were adequately addressed through the inherent resilience of the Project design and the application of standard engineering practice.

The proposed adaptation measures presented Table 11-7 focus on managing flood risk at the temporary onshore support facilities through coordination with the Port of Igoumenitsa and Corfu International Airport operators, taking account of the facilities' existing flood-management, drainage and emergency-response arrangements. Project-specific measures include appropriate location or protection of critical equipment, electrical systems, chemicals, and hazardous materials within the areas allocated for Project use; monitoring of weather and flood warnings; and the timely securing, protection, or relocation of mobile Project equipment where required. Existing drainage and flood-protection arrangements may be supplemented by temporary Project controls where reasonably practicable and agreed with the relevant facility operator. Access and logistics arrangements will be reviewed in response to forecast or actual flooding, with practicable alternative arrangements implemented where required and available.

Measures addressing changes in wind characteristics focus on compliance with the applicable operating limits of the MODU, support vessels, lifting equipment and helicopters. Weather conditions and forecasts will be monitored using the meteorological information and decision-support arrangements available to the Project and its contractors. Weather-sensitive activities, including lifting operations, vessel transfers, offshore transfers and helicopter operations, will be postponed, suspended or rescheduled where applicable limits are approached or exceeded. Deck equipment will be secured, and the well, MODU and associated activities placed in a safe condition where required by forecast or actual adverse weather.

Climate change adaptation is an ongoing process. The effectiveness of the adaptation measures shall be monitored during Project execution through the applicable operational and emergency-management arrangements. The measures shall be reviewed where material changes to the Project, relevant facility arrangements or forecast operating conditions indicate that an adjustment is required.

**Table 11-7: Proposed Climate Change Adaptation Measures**

| CLIMATE-RELATED HAZARD                                                                | CLIMATE CHANGE ADAPTATION MEASURE                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flooding of Onshore Installations (coastal, fluvial, pluvial or groundwater flooding) | Coordinate Project flood-risk arrangements with the Port of Igoumenitsa and the Corfu International Airport operators, taking into account the applicable facility flood-management and emergency-response procedures. |
|                                                                                       | Locate or protect Project-critical equipment, electrical systems, chemicals and hazardous materials taking account of the flood risk within the areas allocated for Project use.                                       |
|                                                                                       | Use existing drainage and flood-protection arrangements at the onshore support facilities, supplemented by temporary Project controls where reasonably practicable and agreed with the relevant facility operator.     |
|                                                                                       | Monitor applicable weather and flood warnings and implement arrangements for the timely securing, protection or relocation of mobile Project equipment and hazardous materials where required.                         |
|                                                                                       | Review access and logistics arrangements in response to forecast or actual flooding and implement practicable alternative arrangements where required and available.                                                   |
| Changes in wind characteristics                                                       | Apply the operational wind limits established for the MODU, lifting operations, vessel transfers and helicopter operations.                                                                                            |
|                                                                                       | Monitor weather conditions and forecasts using the meteorological information and decision-support arrangements available to the Project, MODU, vessels and aviation contractors.                                      |
|                                                                                       | Plan and conduct marine and aviation operations in accordance with applicable weather-related operating limits and procedures.                                                                                         |
|                                                                                       | Use a MODU and support vessels that comply with applicable Flag State, classification and regulatory requirements for the environmental conditions relevant to the Project.                                            |
|                                                                                       | Secure deck equipment in accordance with the MODU's and vessels' applicable procedures for forecast adverse weather.                                                                                                   |
|                                                                                       | Conduct lifting and crane operations within the applicable equipment limits and approved operating procedures, including relevant wind limits.                                                                         |

| CLIMATE-RELATED HAZARD | CLIMATE CHANGE ADAPTATION MEASURE                                                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <p>Postpone, suspend or reschedule offshore transfers, lifting activities and helicopter operations where applicable weather limits are approached or exceeded.</p> <p>Maintain contingency arrangements for temporary suspension of operations and placing the well, MODU and associated activities in a safe condition during adverse weather.</p> |

## 12 Environmental and Social Management and Monitoring

---

The purpose of the Environmental and Social Management and Monitoring Plan (ESMP) is to:

- Present an overview of the Environmental and Social Management System (ESMS) that is being implemented to ensure the systematic and effective execution of Environmental and Social Management (ESM) obligations related to the project's phasing, including preparatory/mobilization, operation, and decommissioning/abandonment phases.
- Provide a summary of the role and responsibilities of Energean and the relevant drilling, marine, aviation, logistics and specialist contractors during each phase of the Project.

The ESMP provides the framework through which the mitigation, management and monitoring commitments established in this ESIA will be assigned, implemented, recorded and verified during Project execution. To this end, the ESMP:

- Identifies and communicates the relevant legal requirements and good practices that will govern the Project's environmental and social management.
- Describes how the Project will apply Energean's existing Health, Safety and Environmental Management System (HSE-MS), together with the relevant contractor and operator management systems, plans and procedures, to deliver the Project safely.
- Defines the arrangements for allocating responsibilities, monitoring performance, maintaining records, managing non-compliances and implementing corrective actions.

The ESMP shall be reviewed before commencement of Project activities and during Project execution where a material change in the Project, applicable requirements, environmental or social risks, contractor arrangements or monitoring results indicates that revision is necessary. Any revision will remain consistent with the approved Environmental Terms and other applicable regulatory requirements. Where a proposed change may affect the assessed Project design envelope or approved Environmental Terms, it will be managed through the applicable management-of-change and regulatory processes before implementation.

The ESMP is supported by relevant Management Plans (MPs), which provide the detailed controls and procedures required for their respective subject areas. These include, as applicable to the Project:

- Waste Management Plan (WMP),
- Chemical Use Plan (CUP),
- Onshore Traffic Management Plan (OTMP),
- Cultural Heritage Management Plan (CHMP).

Relevant MODU, vessel, aviation, logistics and specialist-contractor plans and procedures also apply to the activities under the control of the respective contractor or facility operator. These documents will be aligned with the applicable Project requirements through contractor assurance and bridging arrangements, as appropriate.

## 12.1 Health, Safety and Environmental Management System

Energean will apply its existing HSE-MS throughout the project, in accordance with the ESIA commitments, applicable legal and regulatory requirements, and Energean policy. The HSE-MS will:

- Promote compliance with applicable legislation and regulatory requirements,
- Promote the principles of good environmental practice during routine, non-routine and emergency activities;
- Develop goals and objectives to address significant issues,
- Define the roles and responsibilities of Energean and the relevant contractors, and in particular, the environmental and social obligations applicable to their respective activities;
- Identify the legal requirements, guidelines and good international industry practices applicable to the Project;
- Provide arrangements to verify that Project activities are carried out in accordance with the applicable environmental legal framework, Approved Environmental Terms, and Project procedures;
- Provide clear procedures for managing environmental and social impacts, incidents and non-compliances, including the assignment and close-out of corrective actions;
- Define induction, awareness, and role-specific training requirements,
- Defines a monitoring mechanism in order to:
- Verify the implementation of applicable mitigation measures,
- Monitor the effectiveness of mitigation measures, where appropriate,
- Define environmental monitoring and control requirements,
- Provide a mechanism for timely action in the event of environmental emergencies,
- Define training requirements at the various levels.

This system will be implemented with the aim of maintaining and, where appropriate, improving environmental and social performance. The main elements of the ESMP are the following (as applicable):

- Purpose,
- Project definition and facilities,
- Legislation and guidelines and applicable standards,
- Organizational structure (roles and responsibilities),
- Management plans and operational controls,
- Environmental and social monitoring,
- Notification and documentation,
- Change management,
- Training and awareness program,
- Cultural Heritage Management Plan,
- Waste Management Plan,
- Chemical Use Plan,
- Contractor and supplier management,

- Decommissioning / abandonment,
- Traffic management,
- Incident, non-compliance and corrective-action management; and
- Reporting.

### 12.1.1 Scope

---

The scope of this document includes the activities to be carried out during the implementation of the Project.

The organizational structure of Energean and the main contractors may evolve and change during the implementation of the Project. Roles and responsibilities for implementing the applicable environmental terms and compliance tasks shall be defined and communicated before the relevant activities commence and updated where necessary to reflect the final contracting and operational arrangements.

The requirements and commitments set out in this document are applicable to Energean personnel and to contractors and suppliers to the extent relevant to their respective activities, roles and responsibilities. Contractors and suppliers shall implement appropriate management arrangements and procedures consistent with the applicable Project HSE requirements and ESIA commitments.

The Project-specific HSE arrangements shall be reviewed and updated where necessary to address material changes in applicable environmental, social, occupational health and safety, or working-condition requirements and risks.

### 12.1.2 Project standards

---

The Project shall be managed in accordance with the applicable requirements and commitments identified in Chapter 5 of this ESIA, including, as relevant to the respective activity:

- Energean's HSE Policy,
- National Legislation (L.4014/2011) and all relevant regulations governing national permitting and the expanded environmental protection framework,
- International Convention for the Prevention of Pollution from Ships (MARPOL), as applicable to the MODU, Project vessels and relevant discharge or waste stream,
- International Convention on Oil Pollution Preparedness, Response and Co-operation (OPRC), as implemented through applicable legislation and relevant vessel and Project oil-pollution preparedness and response arrangements,
- Agreement for the Conservation of Cetaceans in the Black Sea, the Mediterranean Sea and the Contiguous Atlantic Area (ACCOBAMS) guidance,
- the Barcelona Convention and its Offshore Protocol, together with applicable decisions, standards and guidelines relevant to offshore exploration activities; and,
- Good Oilfield Practices and Good International Industry Practice (GIIP), where relevant and appropriate to the Project.

Other legislation and international conventions described in Chapter 5, including UNCLOS, the FUND

Convention, the Stockholm Convention and the Aarhus Convention, form part of the broader legal and policy context and shall apply to the Project only to the extent that their requirements are applicable to the Project or have been implemented through applicable EU or Greek legislation.

### 12.1.3 Setting goals and objectives

---

The main purpose of the ESIA is to provide a framework for the implementation of the measures to avoid, mitigate or compensate for adverse environmental and social impacts, as well as to minimize and make manageable the risks to the environment, personnel and the local community.

The HSE during the Project duration will:

- Outline the way Energean will monitor and review the relevant Contractors' performance,
- Define the roles and responsibilities of Energean and relevant Contractors,
- Support implementation of the environmental and social commitments and controls to be established in the Approved Environmental Terms and applicable Project requirements,
- Establish applicable health, safety and working-condition requirements for Project activities,
- Require the relevant Contractors, within the scope of their respective activities, to:
- Identify potential risks associated with their activities and take appropriate measures to reduce and manage those risks,
  - Implement measures to prevent or minimise environmental damage and damage to third-party property,
- Implement the applicable impact-avoidance and mitigation measures; and,
- Perform activities under their control in accordance with applicable legislation, permit conditions, Project interface/bridging documents, Energean's applicable HSE requirements and relevant Good International Industry Practice.

### 12.1.4 Review of energen's health, safety and environmental management system

#### 12.1.4.1 Overview

---

Energean is responsible for overseeing the environmental and social management of the project's activities, with the aim of ensuring the implementation of the applicable Project commitments and compliance with applicable environmental and social legal, regulatory, and corporate requirements.

Energean implements an HSE-MS, which defines the principles to be observed by all employees and contractors associated with the Project.

This Management System is based on internationally recognized good practices in the management of HSE risks in the exploration and production (E&P) industry and is structured around a classic PLAN – DO – ASSESS – ADJUST cycle.

**Figure 12-1: HSE MS**

In this way of managing risks:

- HSE risks associated with the Project's activities are identified and assessed,
- Necessary actions are taken to manage these risks, and the level of risk is reduced to the extent reasonably practicable.
- Performance and the effectiveness of controls are assessed through measurements, monitoring, reviews, audits and investigations, as appropriate,
- Plans and procedures are adjusted based on these assessments, where necessary, and
- Personnel participate in the HSE-MS in accordance with their respective roles and responsibilities.

#### 12.1.4.2 Risk assessment – threat/opportunity identification & risk management

The ESIA and risk assessment of the Project identify the environmental and social risks and potential impacts that require mitigation and control. The identification and assessment of impacts is carried out through a process that includes consultation, process simulations, on-site observations, literature review and experience from similar projects.

Energean and the relevant contractors shall apply, as appropriate, the Health and Safety Control Hierarchy and the Environmental and Social Risk Control Hierarchy. The relevant hierarchy shall be taken into account when developing appropriate mitigation strategies and management measures.

## Hierarchy of Controls

Figure 12-2: Hierarchy of controls for Occupational Health and Safety (OHS) hazards

Figure 12-3: Hierarchy of controls for Environmental and Social Risks

To ensure ongoing risk management throughout the Project, Energean will maintain, or ensure the maintenance of, appropriate Project risk registers. The relevant contractors and operators shall maintain risk assessments and risk registers for the activities under their control, in accordance with their management systems and Project requirements. The applicable risk registers and assessments shall take account of the findings of the ESIA and other relevant Project studies and assessments. Energean and the relevant contractors and operators will ensure that applicable HSE and social risks are systematically identified, assessed and evaluated.

The methodologies for identifying, assessing and analysing risks will be appropriate in relation to their scope, nature and timing. This will support the systematic identification, prioritisation and documentation of risks and the implementation of appropriate control measures. The methodologies used will be in line with applicable Project requirements and relevant Good International Industry Practice. Energean and the

relevant contractors and operators will apply the relevant hierarchy of controls or mitigation hierarchy and the ALARP principle, as applicable, when developing risk-control measures.

Energean and the relevant contractors will ensure that Project personnel are aware of the key environmental, social and occupational health and safety risks applicable to their roles and activities, and of the measures to be implemented. Energean and the relevant contractors shall prepare and maintain risk assessments and risk registers appropriate to the activities under their respective control. Relevant contractor risk assessments, risk registers and supporting information will be made available to Energean for review and assurance in accordance with the applicable contractual and Project arrangements.

Risk information will be communicated to relevant Project personnel and functions, as appropriate to their responsibilities. Energean will review the material environmental, social and HSE risks associated with the Project and the related mitigation and management measures at appropriate stages before and during Project execution, and following a material change, a significant incident, a material monitoring finding, or the identification of a new or materially changed risk.

Figure 12-4: Hierarchy of responsibility for risk management

### 12.1.4.3 Legal and other requirements

The Project compliance framework (Project Standards) is provided in Chapter 5 of this ESIA, which includes an analysis of relevant legislation, national policy and development plans. Compliance with the relevant legislation will be a core commitment of Energean.

Energean will require contractors to identify and comply with applicable legislation and other standards relevant to the E&S management of their activities. It will also require Project personnel to be aware of and comply with legal and Project requirements applicable to their roles and activities. Energean shall maintain the Project-level register of applicable legal and other requirements. Contractors shall maintain any additional legal registers required under their own management systems and notify Energean of material changes in applicable requirements relevant to their Project activities.

## 12.1.5 The Environmental Monitoring and Management System as a management system for Energean

In support of the ESMP, environmental and social management plans will be developed and implemented to manage and mitigate the E&S issues associated with the Project, taking account of Energean's existing HSE management arrangements and the applicable plans and procedures of the relevant contractors. The following table presents the main Project management plans and their indicative scope. The Project's environmental and social management plans will be developed into full plans before commencement of the activities to which they apply, following appointment of the relevant contractors where their input is required and will be reviewed and updated where necessary to reflect final operational arrangements, applicable permit conditions, material changes or relevant findings from monitoring, inspection or incident investigation.

**Table 12-1: Management Plans**

| MANAGEMENT PLAN (MP) / CONTROLS                                       | ISSUE COVERED                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemical Use Plan (CUP)</b>                                        | <ul style="list-style-type: none"> <li>Regulatory framework</li> <li>Register of chemical substances</li> <li>Chemical selection and environmental hazard review</li> <li>Use and quantities</li> <li>Planned discharge routes and quantities, where applicable</li> </ul>                                                                                                                                                                                     |
| <b>Waste Management Plan (WMP)</b>                                    | <ul style="list-style-type: none"> <li>Waste Management requirements and principles</li> <li>Non-Hazardous Waste Management Procedures</li> <li>Hazardous Waste Management Procedures</li> <li>Waste segregation, storage, transfer and shore-reception arrangements;</li> <li>Waste documentation and authorised waste-contractor arrangements; and</li> <li>Monitoring, Reporting and Auditing</li> </ul>                                                    |
| <b>Cultural Heritage Management Plan (CHMP)</b>                       | <ul style="list-style-type: none"> <li>Cultural heritage awareness</li> <li>Chance Finds Procedure</li> <li>Monitoring and reporting, where applicable</li> </ul>                                                                                                                                                                                                                                                                                              |
| <b>Pollution Prevention-Controls</b>                                  | <ul style="list-style-type: none"> <li>Management of atmospheric emissions, noise, discharges, spills and hazardous materials in accordance with the applicable ESIA commitments, contractor and operator procedures, and legal and permit requirements</li> <li>Inspection and maintenance of relevant pollution-prevention equipment</li> <li>Spill prevention and control arrangements</li> <li>Monitoring and reporting required under the ESMP</li> </ul> |
| <b>Environmental and Social Management and Monitoring Plan (ESMP)</b> | <ul style="list-style-type: none"> <li>Project environmental and social commitments and responsibilities</li> <li>Applicable Environmental Terms and other Project requirements</li> <li>Management and monitoring arrangements</li> <li>Training and awareness requirements</li> <li>Contractor coordination and assurance</li> <li>Environmental incident and non-compliance management</li> <li>Reporting and record-keeping requirements.</li> </ul>       |

| MANAGEMENT PLAN (MP) / CONTROLS      | ISSUE COVERED                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Traffic Management Plan (TMP)</b> | <ul style="list-style-type: none"> <li>• Driver competence and journey-management requirements, where applicable</li> <li>• Vehicle movements, routing, loading and unloading within the onshore logistics base,</li> <li>• Vehicle access, parking and coordination with the relevant facility operator,</li> <li>• Risk assessment for cargo transportation, where applicable,</li> <li>• Monitoring and reporting</li> </ul> |

Energean will manage and oversee the environmental and social aspects of the preparatory/mobilisation phase of the Project, monitoring the technical, environmental and social performance of its contractors in accordance with the applicable contractual and Project assurance arrangements. This will be done through the implementation of the Management Plans and the HSE Management System. The contractors will be responsible for managing their personnel and implementing the environmental, social and HSE requirements applicable to the activities under their control, including relevant requirements of the ESMP and supporting Management Plans.

During Project execution, Energean will apply its HSE-MS and the applicable Project management plans to oversee implementation of the ESIA commitments and approved Environmental Terms. Relevant requirements will be incorporated into contractor requirements and aligned with contractor and operator plans and procedures, as appropriate. Environmental and social performance will be monitored and reviewed, and corrective actions or changes to controls will be implemented where required.

### 12.1.6 Other related HSE's MPs

The drilling rig used for the Project will implement the drilling contractor's applicable HSE management system, plans and procedures. The rig's plans, procedures and reporting requirements will be reviewed and aligned with the applicable Project HSE requirements and ESIA commitments through the relevant contractor-assurance and bridging arrangements.

Energean and the drilling contractor shall establish agreed HSE objectives, responsibilities, interfaces and reporting requirements for the Project, while retaining their respective management systems and responsibilities for the activities under their control.

Drilling monitoring and reporting will be carried out in accordance with applicable legal and permit requirements, the ESIA commitments, Project procedures and the drilling contractor's relevant environmental procedures. The applicable procedures will define the method and frequency of monitoring, recording and reporting for the following categories, as relevant to the Project and the systems installed on the selected MODU:

- Bilge water, deck drainage and wash water, sewage and oily-water management, and associated discharge or transfer records,
- Fuel consumption records,
- Drilling fluid management, cuttings, and relevant water-based mud (WBM) properties,
- Waste retained onboard and transferred to shore,
- Drilling, cementing, and any other chemicals used for planned or contingency well operations,

- Environmental sampling and labelling of drilling fluids or cuttings, where required under the Environmental and Social Monitoring Plan,
- Drilling chemicals reporting,
- Reports of environmental accidents, incidents, and spills,
- Well-completion environmental report, where required by the approved Environmental Terms or other applicable regulatory requirements.

Auditing and review are key elements of Energean's and the drilling contractor's HSE management arrangements. Audits and inspections shall be undertaken in accordance with the applicable Project and contractor assurance programmes. Additional audits and inspections may be carried out to address identified areas of concern. Joint audits may be carried out where appropriate to verify implementation of applicable Project requirements and agreed interfaces. Energean and the drilling contractor shall maintain arrangements for communication and for recording, assigning and tracking applicable audit and inspection actions to close-out.

### 12.1.7 Roles and responsibilities

---

Energean is responsible for the design, procurement, preparatory activities and overall coordination and oversight of the proposed Project. As the Project Owner, Energean will have ultimate responsibility for overseeing the implementation of the ESMP, which will include:

- Ongoing management of environmental and social issues that arise as the detailed design progresses,
- Monitoring and auditing the relevant aspects of Contractors' performance in relation to HSE (including working conditions),
- Coordinating and overseeing implementation the implementation of the ESMP and specific management plans,
- Acting as a point of contact for consultation with the competent Authorities and relevant stakeholders,
- Monitoring and reporting on environmental and social compliance,
- Establishing requirements for contractors and verifying their performance against applicable Project requirements and regulations,
- Recording of compliance and non-compliance with the applicable requirements of the ESIA.

The relevant contractors of the project will be required to comply with the environmental, social and HSE requirements applicable to their respective activities, which will provide the framework for managing social and environmental issues throughout the project's implementation.

The main contractors will be required to develop and implement the plans and procedures necessary for the activities under their control, consistent with the applicable requirements of the ESMP and agreed bridging/interface document. The ESMP and applicable supporting Management Plans will be used to fulfil the commitments of the Project's ESIA and to coordinate and review the Project's environmental and social performance during the project's implementation. Particular attention will be paid to the following:

- Practical training and increasing environmental and social awareness of personnel,
- Supervision and monitoring of environmental and social issues,

Each Contractor will be responsible for:

- Complying with applicable environmental legislation, permit conditions and Project requirements;
- Demonstrating how the requirements applicable to their activities will be implemented;
- Implementing the applicable requirements of the ESMP, Bridging/Interface Document, and Energean's HSE-MS, including through their subcontractors;
- Identifying and complying with changes in legal and regulatory requirements applicable to their activities; and
- Providing information necessary to support updates to the ESMP, where required. Updates to the ESMP shall be controlled and approved by Energean.

## 12.1.8 Training

### 12.1.8.1 Introduction

---

Environmental training will help ensure that the requirements of the ESIA and ESMS are understood and adhered to by Project personnel as applicable to their roles and activities. Environmental training will form part of the environmental management system. General environmental awareness training will be included in the Project induction or other relevant briefing provided to personnel whose activities may affect environmental or social performance.

Within the framework of the ESMS, role-specific training or briefings will be provided to personnel responsible for implementing mitigation measures, environmental monitoring, inspections, reporting or emergency response.

The training will apply to all relevant Project phases. Training topics may include, as applicable to the person's responsibilities:

- Training on specific topics (in accordance with the interface/bridging document),
- Environmental controls relevant to the work activity,
- Monitoring and control,
- Record keeping,
- Stakeholder communications, for personnel assigned such responsibilities,
- Emergency situations,
- Health and safety.

#### 12.1.8.2 Objectives of the training program

---

The main objective of the training program is to ensure that the requirements of the ESIA applicable to Project personnel's roles and activities are clearly understood and adhered to throughout the Project. Staff training will contribute to the communication of the environmental controls set out in the ESIA.

#### 12.1.8.3 Roles and responsibilities

---

Energean will define the Project-level environmental training and awareness requirements. Each contractor will be responsible for providing its personnel with the induction, training and briefings applicable to their assigned activities, using suitably competent personnel.

Contractors will be required to provide the applicable induction or briefing to their personnel before they commence relevant Project activities.

#### 12.1.8.4 Training log

---

A training record will be maintained by Energean and the contractor(s). The training record will include, as appropriate:

- Topic,
- Date, time and location,
- Trainer, and
- Participants.

#### 12.1.8.5 Educational needs assessment

---

Additional training or briefing will be provided where a training need is identified. The criteria for assessing the need for additional training or briefing may include:

- Introduction of new personnel whose activities require Project-specific training,
- When repeated or material non-compliance is reported, where retraining is an appropriate corrective action,
- Following an incident where investigation identifies a training or awareness deficiency,
- Upon the arrival of a new contractor/subcontractor, where Project-specific requirements apply to its activities,
- Upon the start of a new activity or material change in working arrangements requiring additional competence or awareness.

#### 12.1.8.6 Educational material

---

Energean will provide the relevant Project environmental and social requirements to contractors. Each contractor will use or prepare training and briefing materials appropriate to its personnel's activities and

responsibilities. Separate training materials may be prepared for each topic, where necessary. Table 12-2 presents the indicative training topics.

**Table 12-2: Indicative scope of training program**

| STAFF                                                                                                      | CONTENTS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | TIMELINE                                                 |
|------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Selected management personnel and contractor(s) / subcontractor(s)</b>                                  | <ul style="list-style-type: none"> <li>• Environmental and social sensitivity of the Project area</li> <li>• Key findings of the ESIA relevant to their responsibilities</li> <li>• Mitigation measures</li> <li>• Monitoring and control, where assigned</li> <li>• Record keeping, where assigned</li> <li>• Stakeholder communications, where assigned.</li> <li>• Emergency arrangements relevant to their roles</li> <li>• Applicable Health and safety requirements</li> </ul>                                | Before undertaking the relevant Project responsibilities |
| <b>Project personnel whose activities are subject to Project-specific environmental or social controls</b> | <ul style="list-style-type: none"> <li>• Environmental and social sensitivity of the Project area</li> <li>• Key findings of the ESIA</li> <li>• Good operating procedures</li> <li>• Mitigation measures</li> <li>• Waste management requirements relevant to their activities</li> <li>• Site management</li> <li>• Monitoring and control, where assigned</li> <li>• Record keeping, where assigned</li> <li>• Applicable Emergency arrangements</li> <li>• Applicable Health and safety requirements</li> </ul> | Before commencing the relevant Project activities        |

#### 12.1.8.7 Training during preparatory / mobilization phase

During the preparatory/mobilisation phase, contractors shall be responsible for the training of their personnel. Contractors shall ensure that personnel have the qualifications, competence and skills appropriate to their assigned activities.

Contractors shall use their existing training and competence arrangements to address applicable Project requirements. Where a contractor prepares a Project-specific Training Plan, it should address, as applicable:

- Induction training program for relevant personnel,
- Activity-specific training requirements,
- Applicable requirements for subcontractor personnel,
- Training records.

Applicable Management Plans shall identify any specialist training, competence or awareness requirements necessary for their implementation.

#### 12.1.8.8 Training during the drilling and decommissioning / abandonment phases

Training during drilling and decommissioning / abandonment phases will be provided according to the activities and responsibilities of relevant personnel, including, as applicable:

- Relevant Project and contractor management personnel,
- Drillship Personnel,
- Platform Supply Vessel (PSV) Personnel,
- HSE and specialist personnel.

Emergency response exercises will be conducted in accordance with applicable Project, MODU and vessel emergency-response procedures and regulatory requirements. Applicable Management Plans shall identify any specialist training, competence or awareness requirements necessary for their implementation.

### 12.1.9 Communications

#### 12.1.9.1 Communications during preparatory / mobilization phase

##### Communication between Energean and the Contractor(s)

During the preparatory/mobilisation phase, appropriate communication and reporting arrangements shall be established between Energean and the relevant contractors. Contractors shall, as applicable to their activities:

- Inform Energean in advance of the schedule, progress and key Project activities.
- Inform Energean promptly of planned visits or inspections by representatives of the competent authorities, where known, and of material regulatory enquiries relating to the Project;
- Inform Energean before planned Project-related meetings with the competent authorities, except where direct communication is required by law, permit conditions, safety, emergency or routine operational arrangements;
- Communicate to Energean any Project-related concerns received from external stakeholders;
- Maintain appropriate records of material Project-related regulatory and stakeholder communications; and
- Communicate with other contractors, where necessary, using the applicable Project coordination and communication arrangements.

##### Contact with Authorities

Energean shall coordinate Project-level communications with the competent authorities, including, as applicable, HEREMA, the Port Authorities, Hellenic Coast Guard, Civil Aviation, Marine Antiquities.

Contractors will inform Energean before planned Project-related engagement with the competent authorities. This will not restrict communications required under applicable law, permits, vessel or aviation procedures, emergency-response arrangements, or the independent statutory and safety responsibilities of the relevant contractor, operator, OIM or vessel Master. Energean will be informed promptly of any material communication made through those routes.

#### Communication with interested third party

Planned external communications concerning the Project shall be coordinated with Energean. This requirement does not restrict routine operational communications, navigational or aviation communications, emergency notifications, legally required reporting, or communications necessary to protect health, safety or the environment.

### 12.1.9.2 Communications during drilling and decommissioning / abandonment phases

---

#### Communication with authorities

Energean will coordinate Project-level communications with the competent authorities, including, as applicable, the Port Authorities, Hellenic Coast Guard, civil aviation authorities and Ephorate of Underwater Antiquities. The relevant contractors, operators, OIM and vessel Masters may communicate directly with the competent authorities where required by applicable law, permits, operational procedures or emergency-response arrangements. Energean will be informed promptly of material Project-related communications through those routes.

#### Communication with interested third party

Planned external communications concerning the Project will be coordinated with Energean. This requirement does not restrict routine operational communications, navigational or aviation communications, emergency notifications, legally required reporting, or communications necessary to protect health, safety or the environment.

## 12.1.10 Change management

### 12.1.10.1 Overview

---

Although the Project design and execution arrangements will continue to be developed, changes may arise during mobilisation, drilling preparation, drilling, decommissioning/abandonment that need to be addressed in a structured manner. Changes arising after submission or approval of the ESIA shall be assessed according to their nature and potential environmental and social implications. The main legal framework in Greece for the environmental permitting of Project modifications is the provisions set out in Law 4014/11 as supplemented by the relevant Joint Ministerial Decisions (JMD). Energean will follow the regulatory framework and the actions required will be determined according to the nature and potential environmental implications of the proposed change:

- Minor modifications usually do not require new or advanced environmental studies, but only environmental reports and notifications to the competent Authorities. Changes to the ESIA will likely be minimal.
- Moderate changes usually require Reports for Modification of the Approved Environmental Terms or even a new ESIA. In such a case, a revision of certain sections of the ESIA is required.
- Major changes require a new ESIA.

#### 12.1.10.2 Emergency preparedness and response

---

Energean will require the Project team and relevant contractors to identify potential emergency situations associated with the activities under their control and respond to these situations in an appropriate manner, to prevent or mitigate potential adverse environmental and social impacts.

Energean will require that the needs and interfaces of relevant stakeholders, including emergency services, competent authorities and neighbouring facility operators (if applicable), are considered as part of this process, and that emergency arrangements are reviewed, tested and revised in accordance with applicable Project, contractor, MODU and vessel procedures and regulatory requirements.

For the drilling phase, Energean and the relevant contractors will maintain the emergency-response procedures applicable to their respective responsibilities and activities. These procedures will be in place before commencement of the activities to which they apply and tested through drills and exercises at the frequencies defined in the applicable interface/bridging documents, emergency-response arrangements, and regulatory requirements. Relevant personnel will receive appropriate training.

Energean will review and monitor the performance of relevant contractors and the interfaces between the applicable emergency-response plans through the Project assurance process and following material exercises, incidents or changes, where appropriate.

During the drilling and decommissioning/abandonment phases, emergency preparedness and response will be managed through the applicable Project, MODU, vessel and contractor emergency-response arrangements, with Energean providing Project-level coordination, oversight and regulatory interface, taking account of the Project Qualitative Risk Assessment and Report of Major Hazards.

For the project's requirements, Energean will develop a dedicated Emergency Response Plan (ERP) which will be appropriately submitted to the regulatory authorities for review and approval.

#### 12.1.11 Contractor and supplier management

---

All contractors and suppliers shall comply with the HSE requirements set out in their respective contracts, including the applicable HSE appendices. Contractors will also comply with the applicable Project's interface and bridging documents. Contractors will maintain and implement their own HSE management systems, plans and procedures appropriate to the activities under their control and aligned with the applicable contractual and bridging requirements.

Contractors and suppliers will comply with the legal and regulatory duties and responsibilities applicable to their respective activities and personnel, including applicable national, EU and international requirements in relation to OHS and labour issues.

Energean will provide contractors and suppliers with the Project information and requirements relevant to their respective scopes and undertake assurance of compliance with the applicable contractual and bridging requirements, proportionate to the nature and HSE risk of the contracted activities or services.

## 12.1.12 Environmental monitoring and reporting

### 12.1.12.1 Environmental compliance monitoring

---

Compliance monitoring will be carried out to verify compliance with the applicable requirements of the ESIA. The objectives of ESIA compliance monitoring will be:

- Monitoring Project activities with material environmental or social requirements,
- Verifying compliance of Project activities with the ESIA, the ESMP, the HSE Management System and other applicable Project requirements,
- Recording and communicating observations to the relevant Energean and contractor personnel, so that timely corrective measures can be taken, if required,
- Keeping a record of incidents of environmental significance and the related actions and corrective measures.

Compliance monitoring will be the responsibility of Energean and the relevant contractors and subcontractors, according to their respective activities and responsibilities. It will include, as appropriate:

- Monitoring by Energean HSE personnel or other designated Energean representatives; and
- Monitoring by designated personnel of the relevant contractors or subcontractors.

During compliance monitoring, the following matters may be checked, as applicable to the activity and monitoring purpose:

- Visible atmospheric emissions and unnecessary engine operation;
- Fuel and water consumption records;
- Waste management, including hazardous and non-hazardous waste;
- Noise-related controls or measurements where required by the ESIA, applicable procedures or in response to a specific concern;
- Project-related environmental concerns received through the applicable stakeholder communication arrangements;
- Environmental incidents, spills and discharges;
- Chemical use; and
- Implementation of applicable mitigation measures.

The proposed Monitoring Program is set out in Section **12.2.2**

### 12.1.12.2 Complaints register

---

The Head of Corporate Affairs & Communications will maintain a register of Project-related concerns received through the applicable stakeholder communication arrangements and the actions taken in response. Material Project-related concerns will be forwarded to the appropriate Energean representative for further action, where required.

### 12.1.12.3 Photographic archive

Energean will maintain a photographic record, where appropriate, of relevant onshore areas allocated for Project use and material environmental observations made during Project activities. The photographic record will include, where relevant, photographs taken before and after Project use of temporary onshore areas, and photographs supporting environmental inspections, incident investigations or completion records. Material environmental non-compliances will be photographed where practicable and relevant to documenting the condition, corrective action or close-out.

### 12.1.12.4 Audit reports

As part of Energean's responsibilities, Energean HSE personnel or other designated representatives will conduct environmental inspections at a frequency appropriate to the activities, environmental risks and findings from previous inspections.

Routine workplace inspections will also be undertaken by the relevant contractors in accordance with their procedures. The areas listed in Table 12-3 will be checked where applicable to the location and activities being inspected.

**Table 12-3: Indicative Environmental Inspection Items**

| CONTROLS THROUGH OBSERVATION                                                                                  |
|---------------------------------------------------------------------------------------------------------------|
| Waste storage and management                                                                                  |
| Separation of solid waste into the applicable waste streams (general, hazardous, recyclable, waste materials) |
| Leaks and spills                                                                                              |
| Effectiveness of applicable environmental control measures                                                    |
| Stormwater drainage and wastewater management, where applicable;                                              |
| Water use                                                                                                     |
| Evidence of pollution or loss of containment; and                                                             |
| Any activities not compatible with the WMP or other applicable Project environmental requirements.            |

The relevant contractors will undertake inspections within the areas and activities under their control. The scope may include, as applicable:

- Implementation of the Environmental and Social Monitoring Plan,
- Relevant onshore and offshore work areas,
- Environmentally sensitive areas that could be potentially affected, where access and inspection are relevant and practicable,
- Waste storage facilities, including areas for general, hazardous and recyclable waste,
- Waste staging areas.

Energean will maintain Energean audits and inspections, together with relevant contractor audit and inspection records provided through the Project assurance arrangements, carried out to verify compliance with the ESMP.

#### 12.1.12.5 Disclosure and documentation

An effective mechanism for storing and communicating environmental information during the Project is essential. The key features of such a mechanism are:

- Accurately recording and maintaining monitoring information and records required by the ESMP, applicable permits and Project procedures,
- Sharing the information in a central (digital) location, accessible to relevant Project personnel,
- Processing the information to produce reports at the frequencies required by the ESMP, applicable permits and Project procedures, and
- Providing information to the competent authorities and other stakeholders in accordance with applicable legal requirements, permit conditions and Project communication arrangements.

#### 12.1.12.6 Meetings

The applicable ESMP requirements, responsibilities, interfaces and reporting arrangements shall be incorporated into the relevant HSE interface and bridging documents and communicated to relevant Project and contractor personnel before commencement of the activities to which they apply.

During operations, environmental performance will be included in the weekly HSE meetings. The review will cover, as relevant, monitoring and inspection findings, environmental incidents and non-compliances, stakeholder concerns, and the status of corrective actions. Material findings, decisions and actions will be recorded through the applicable meeting minutes or action-tracking arrangements.

#### 12.1.13 Non-Compliance incident management

Energean HSE personnel and relevant contractor personnel shall conduct inspections within their respective areas of responsibility to identify non-compliances. Where a non-compliance is identified, the finding shall be recorded and communicated to the responsible Energean and contractor personnel. Appropriate corrective actions will be assigned, tracked and closed out in accordance with the applicable Project and HSE procedures.

Incidents shall be promptly reported and investigated in accordance with the applicable HSE procedures, taking account of their actual or potential significance. All personnel will report incidents and near misses through the applicable reporting route, in accordance with their employer's HSE procedures and the applicable Project interface and bridging arrangements.

Incidents and non-compliances related to the Project shall be reported through the applicable contractor and Project reporting arrangements and communicated to Energean where required. Energean and the relevant contractors will maintain procedures for incident reporting, investigation, corrective and preventive action, where appropriate, and close-out, with the applicable reporting lines and responsibilities defined in the relevant HSE interface and bridging documents. Exceedances of applicable environmental standards, permit limits or defined Project thresholds shall be recorded and managed as incidents or non-compliances, as appropriate to their nature and significance.

Incident and non-compliance reporting procedures shall be communicated to relevant personnel as part of the applicable Project induction or briefing before they commence Project activities.

#### 12.1.14 Report writing

---

Energean will ensure that material environmental monitoring, inspection, incident and compliance information is recorded through the applicable Project reporting and action-tracking arrangements. Environmental performance will be addressed through the weekly HSE meeting records during operations. Additional reports will be prepared where required by the ESMP, applicable permits or regulatory requirements, or to support material incident investigations, audits and Project completion reporting.

### 12.2 Environmental and social monitoring

#### 12.2.1 Introduction

---

The implementation of the ESIA will aim to comply with the applicable ESIA commitments, approved Environmental Terms and other regulatory requirements. Compliance assessment will be carried out by:

- Monitoring implementation of applicable mitigation measures,
- Verification of the effectiveness of the measures, where appropriate,
- Record keeping,
- Reporting in accordance with the applicable Project and regulatory requirements.

Within the framework of the ESIA, monitoring arrangements and parameters are established to:

- Verify the implementation of mitigation measures,
- Assess the effectiveness of the mitigation measures,
- Define the requirements for environmental monitoring and control,
- Support the timely identification and management of material environmental deviations or adverse effects.

The monitoring programme will assist in verifying whether the impacts of the Project are within the levels anticipated in the ESIA and will provide information to support timely action where a material deviation or unacceptable impact is identified. For each component of the monitoring programme, the following information will be presented, as applicable:

Relevant ESIA commitment or monitoring objective;

- Responsible party;
- Monitoring parameters;
- Monitoring frequency or trigger; and
- Monitoring method and location.

Monitoring of key environmental and social parameters is intended to support compliance verification and, where appropriate, assessment of Project-related effects during the drilling preparation and mobilisation,

drilling and decommissioning/abandonment phases. The monitoring process will allow Energean to identify changes in the environmental performance of the Project and determine whether corrective actions or adjustments to the environmental and social management arrangements are required.

Monitoring will be undertaken by Energean and the relevant contractors or specialist service providers in accordance with the responsibilities assigned in the Environmental and Social Monitoring Plan. Energean will provide Project-level oversight of the monitoring programme. The applicable monitoring techniques and frequencies are presented in Section 12.2.2 and may be refined where required by the approved Environmental Terms, competent authorities, final operational arrangements or material monitoring findings.

## 12.2.2 Proposed environmental and social monitoring plan

The Monitoring Plan for the Asopus-1 Exploration Drilling Project in Block 2 has been developed taking account of applicable legal and regulatory requirements, relevant Good International Industry Practice and, to the extent applicable to the Project, the provisions set out in YPEN SEA Approval No. 30373/2017. It incorporates the relevant baseline sensitivities and potential environmental risks identified in the ESBS (see Annex 02) and ESIA reports. Should new applicable legal or regulatory obligations emerge, the Environmental and Social Monitoring Plan will be reviewed and updated as necessary.

Table 12-4 presents the proposed Environmental and Social Monitoring Plan for the Project, covering applicable compliance monitoring and environmental-effects monitoring during the drilling preparation and mobilisation, drilling, and decommissioning/abandonment phases.

The proposed Monitoring Plan, will be carried out during drilling campaign as well as following the completion of the operations (plug & abandonment and demobilisation).

The results of the monitoring programme will be recorded and reported in accordance with the requirements specified in Table 12-4 and any applicable legal, regulatory or permit requirements. Where required by the approved Environmental Terms or other applicable regulatory requirements, an Environmental and Social Monitoring Report will be submitted to the competent authority and monitoring information will be made publicly available in the required form.

**Table 12-4: Environmental and Social Monitoring Plan for the Asopus Exploration drilling Project in Block 2**

(Note: The sampling stations and methodologies defined in this monitoring plan are derived from the Phase 2 Environmental and Social Baseline Study (ESBS) report (Annex 02 of this ESIA) to ensure comparability of operational and post-drilling results with pre-drilling baseline conditions.)

| ITEM NO.   | ENVIRONMENTAL / SOCIAL PARAMETER        | INDICATOR                                 | MEASURABLE PARAMETERS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | SAMPLING / OBSERVATION METHODOLOGY                                                                                                                                                                                                                                                                                        | SAMPLING / OBSERVATION FREQUENCY                                                                                               | LOCATIONS & SPATIAL EXTENT                                                                                                                                                                                                |

# 13 Elements of regulatory approval and proposed environmental terms for approval

## 13.1 Type and scale of activity

The Project title is Hydrocarbon Exploration program - Exploration Well Asopus-1 in Block 2 – Ionian Sea.

The activity aligns with the respective Strategic Environmental Assessment (SEA) for E&P in the Ionian Sea (covering the eleven (11) Concession Blocks including also Mesiniakos and Lakonikos Gulfs) that was prepared in 2016 and a respective approval was granted in 2017 (DIPA/MoEE 30373/3.7.2017). The Project comprises the drilling of one offshore exploration well (Asopus-1) within Block 2 in the Ionian Sea. The objective of the proposed activity is to evaluate subsurface geological formations and assess the potential presence of hydrocarbons. The well will be drilled using a mobile offshore drilling unit (MODU), which is purpose-designed for deep-water drilling operations, utilising shore base for logistics support (Igoumenitsa Port) and Corfu Airport (CFU) for transport.

The proposed activity is temporary and limited in scope, comprising the drilling, evaluation, and subsequent plugging and abandonment of the exploration well in accordance with applicable regulatory requirements and industry good practices.

No oil or gas well testing or production is currently planned as part of this activity and thus of the present ESIA. If hydrocarbons are identified, any further appraisal or development activities would be subject to separate permitting and environmental assessment processes in line with all respective EU and National legislative frameworks.

## 13.2 Geographical location

The Concession Area of Block 2 is governed by a hydrocarbons lease agreement with the Hellenic Republic. The Lease Agreement (the “Lease Agreement”), dated 31 October 2017, grants exploration and exploitation rights for Block 2. The Lease Agreement was ratified by the Hellenic Parliament under Law 4525/2018 and published in GG No. 47/A/15.03.2018.

The proposed Asopus-1 exploration well is located within the Block 2 license area in the Greek Exclusive Economic Zone (EEZ) in the northwestern Ionian Sea. It is approximately 44.3 km (23.9 nautical miles) offshore Othonoi Island, approximately 3.2 km (1.7 nautical miles) from the Italian Exclusive Economic Zone (EEZ) and in water depths of approximately 840 m. There are no islands, coastal features, or fixed subsea installations in the immediate vicinity of the well location.

The indicative well location, including geographic coordinates and water depth, is provided in Table 1-2. The coordinates represent the planned seabed location of the well and the anticipated bottom hole position for the exploration programme.

Coordinates are provided using the World Geodetic System 1984 (WGS 84) datum, which is the standard reference system used for offshore operations in the region. The location lies within UTM Zone 34N.

**Table 13-1: Coordinates and Water Depth of proposed Asopus-1 exploration well**

| WELL            | LEASE AGREEMENT | LATITUDE         | LONGITUDE        | WATER DEPTH |
|-----------------|-----------------|------------------|------------------|-------------|
| <b>Asopus-1</b> | Block 2         | 39° 37' 25.92" N | 18° 57' 28.51" E | ~ 840 m     |

The Project will utilise two existing onshore support facilities for logistics and aviation activities:

- (i) an onshore logistics / supply base located within the Port of Igoumenitsa (mainland Greece) appropriately designated under a lease agreement with Port Authority of Igoumenitsa (OLIG SA) and in accordance with the overarching AEPO (initially granted by virtue of JMD 144974/08.06.2005) and lastly updated by virtue of Decision ΥΠΕΝ/ΔΙΠΑ/12891/794/17.03.2022), as currently supplemented to fit the specific project “Asopus-1” support operations; and
- (ii) Corfu International Airport (CFU), which will be used as the helicopter operations base for personnel transfers between the onshore environment and the Mobile Offshore Drilling Unit (MODU), under permission / agreement with CFU’s operator (Fraport GR), which operates under AEPO initially granted by virtue of MD 11945/08.03.2017 and lastly updated by virtue of Decision ΥΠΕΝ/ΔΙΠΑ/123235/8107/23.11.2022)

The shore base incorporates zoning to minimise environmental risks, including spill sensitive quayside areas, controlled storage zones, quarantine areas, laydown areas and defined traffic corridors.

Corfu International Airport (CFU) will provide the aviation logistics hub for routine crew transfers (and where applicable, emergency responses such as medical evacuation) in accordance with the airport’s routine operations.

The following tables, present the coordinates of the onshore logistics support base as well as Corfu Airport (CFU).

**Table 13-2: Coordinates of the proposed logistics support base**

| ONSHORE LOGISTICS SUPPORT BASE | LATITUDE (WGS84) | LONGITUDE (WGS84) | X (ΕΓΣΑ 87) | Y (ΕΓΣΑ 87)  |
|--------------------------------|------------------|-------------------|-------------|--------------|
| Igoumenitsa Port (Area 1)      | 39° 29' 04.24" N | 20° 15' 19.01" E  | 177.765,45  | 4.376.956,26 |
| Igoumenitsa Port (Area 2)      | 39° 29' 06.29" N | 20° 15' 34.34" E  | 178.134,34  | 4.377.004,21 |

**Table 13-3: Coordinates of the proposed aviation logistics base (CFU)**

| AVIATION LOGISTICS BASE (CFU)     | LATITUDE (WGS84) | LONGITUDE (WGS84) | X (ΕΓΣΑ 87) | Y (ΕΓΣΑ 87)  |
|-----------------------------------|------------------|-------------------|-------------|--------------|
| Corfu International Airport (CFU) | 39° 36' 07" N    | 19° 54' 42" E     | 148.794,88  | 4.391.282,96 |

During drilling operations, a temporary 500 m safety zone will be established around the drillship at the Asopus-1 well location to ensure navigational safety and safe conduct of offshore operations. The establishment of the safety zone will be communicated through official maritime notifications, including NAVTEX messages and Notices to Mariners, issued by the Hellenic Coast Guard.

### 13.3 Project classification

According to Ministerial Decision DIPA/37674/10-8-2016, as amended by Ministerial Decisions 2307/2018 and YPEN/DIPA/17815/1069/2022 (GG 841/B' 24.2.2022) and currently in force, the main drilling activity in Asopus-1 falls under **Category 5** "Mining and similar activities", Serial **Number 7** "Extraction of hydrocarbons and exploratory drilling in search of hydrocarbons" and is included in Subcategory **A1** since all works of this activity are classified as such.

In addition, the onshore support facilities in Igoumenitsa Port, fall under Category 3 "Port infrastructure", Serial Number 2a "Ports and port facilities for support of industrial activities (e.g. support of industrial facilities, fuel handling, petrochemicals or chemicals, toxic and harmful substances, quarry products, etc.)" and are classified under Subcategory A2.

### 13.4 Project owner

The Project Owners are Energean Hellas Ltd. (Operator), on behalf of the co-lessees Energean Hellas Ltd ExxonMobil Exploration and Production Greece (Crete) B.V. and HelleniQ Upstream West Kerkyra S.A.

### 13.5 Institutionally designated key characteristics of the project area and environmental sensitive features

#### 13.5.1 Spatial planning and land uses

The spatial planning framework applicable to the wider area of the Project is defined:

- By the National Maritime Spatial Strategy (NMSS), approved by Act of the Cabinet 6/17.04.2025 (GG D 227/2025), which recognizes objective for the promotion of maritime development and a potentially important activity contributing to national energy security and energy supply objectives and emphasizes that any hydrocarbon-related activities should be planned, developed, and implemented in a manner that minimizes adverse impacts on both the natural environment and human activities, ensuring compatibility with environmental protection objectives and other maritime uses.
- By designation of Maritime Spatial Unit (MSU 4), which covers the maritime area of western Greece, including the Adriatic, Ionian Sea, and Central Mediterranean marine regions where Greece exercises sovereign rights and jurisdiction in accordance with national legislation by virtue of MD YPEN/ΔΧΩΡΣ/43090/574/17.04.2025 (GG D 229/2025),
- By the General Framework for Spatial Planning and Sustainable Development (GFPSSD) (GG 128/A/03-07-2008), with whose strategic choices and directions the Project is compatible.
- By the Revised Regional Spatial Framework of the Region of Epirus, adopted by Ministerial Decision YPEN/ΔΧΩΡΣ/78523/1208 and published in GG 286 ΑΑΠ/28-11-2018.
- By the Special Framework for Spatial Planning and Sustainable Development for Industry (Joint Ministerial Decision 11508/2009, GG 151/AAP/13-4-2009), with whose choices and directions the Project is compatible.
- By the Special Framework for Spatial Planning and Sustainable Development for Renewable Energy Sources (Joint Ministerial Decision 49828/2008, GG 2464/B/2008).

- By the Special Framework for Spatial Planning and Sustainable Development for Aquaculture (GG 2505/B/2011).

### 13.5.2 Land uses

The existing and proposed Port Zone boundaries are maintained in accordance with the Igoumenitsa Port Master Plan and the decisions of the Port Planning and Development Committee (ESAL), namely *Decision 02/10.12.2002* of the 4th ESAL Session and *Decision 02/17.12.2004* of the 15th ESAL Session.

Permitted uses within the Port Zone include port facilities, infrastructure, and associated developments in accordance with Ministerial Decision 8216/126/14 “ Revision of the Port Master Plan of Igoumenitsa”.

### 13.5.3 Environmental sensitivity features of the project area

#### 13.5.3.1 National protected areas

The Project does not overlap any area of the Natura 2000 network or any other legally designated protected area.

The nearest Natura 2000 sites to the Exploration Well Asopus-1 are GR2230010 'Marine Area of the Diapontia Islands' and GR2230008 'Diapontia Islands: Othoni, Ereikousa, Mathraki and Rocky Islets', both approximately 41 km from the well.

The nearest Natura 2000 sites to the Igoumenitsa shore base are GR2120001 'Ekvoles (Delta) Kalama' and GR2120005 'Ygrotopos Ekvolon Kalama kai Nisos Prasoudi', approximately 3.5 km from the proposed facilities.

#### 13.5.3.2 International protected areas

The proposed exploration well falls within the Ecologically or Biologically Significant Marine Area (EBSA) 'South Adriatic Ionian Strait'. This EBSA area encompasses the transition zone between the southern Adriatic Sea and the northern Ionian Sea, including the Otranto Channel, with water depths ranging approximately from 200 m to 1,500 m. The designation recognizes the ecological importance of the area as habitat for Cuvier's beaked whale (*Ziphius cavirostris*), giant devil ray (*Mobula mobular*), striped dolphin (*Stenella coeruleoalba*), Mediterranean monk seal (*Monachus monachus*), and loggerhead sea turtle (*Caretta caretta*). The area also supports highly migratory species, including tuna (*Thunnus thynnus*) and swordfish (*Xiphias gladius*), as well as pelagic sharks and deep-sea benthic communities, including cold-water corals and sponge aggregations.

The project does not overlap any other area currently under any international designation status. In particular:

- The Hellenic Trench EBSA is located further south of the Project area, approximately 187 km from the Asopus-1 exploration well.
- The closest designated Important Marine Mammal Area (IMMA) to the project area is the Ionian

Archipelago IMMA, located approximately 37 km east of the Asopus-1 exploration well.

- The closest Cetacean Critical Habitat (CCH) to the project area is the Sazani Island-Karaburun Peninsula, located approximately 72 km north from the proposed exploration well 'Asopus-1'.
- The closest Important Shark and Ray Area to the project area is the Santa Maria di Leuca ISRA, located approximately 20 km west/southwest from the exploration well 'Asopus-1'.
- The closest Key Biodiversity Area to the project area is the Diapontia islands (Othonoi, Ereikousa, Mathraki) and surrounding islets KBA (2943), located approximately 40 km northeast from the exploration well.
- The Marine Protected Areas (MPAs) within the wider region include designated sites across Greek, Italian, and Albanian waters. Within Greek waters, the closest MPA to the well is the Marine Area of the Diapontia Islands MPA, located approximately 43 km to the northeast. Additional MPAs within the Greek Ionian include the Coastal marine zone from Kanoni to Mesongi (approximately 81 km east), the Paxoi and Antipaxoi Islands and the wider marine area MPA (approximately 93 km southeast), and the Lefkimmi salt pans MPA (approximately 97 km east). In Italian waters to the northwest, the closest site is the Costa Otranto–Santa Maria di Leuca MPA (approximately 53 km away). Other MPAs along the Italian coastline include the Posidonieto Capo San Gregorio–Punta Ristola MPA (approximately 57 km away), the Litorale di Ugento MPA (approximately 66 km away), the Alimini MPA (approximately 69 km away), the Litorale di Gallipoli e Isola S. Andrea MPA (approximately 80 km away), the Le Cesine MPA (approximately 93 km away), and the Montagna Spaccata e Rupi di San Mauro MPA (approximately 96 km away). In Albanian waters to the north, the Karaburun–Sazan Marine National Park is located approximately 79 km away. Further east, the Butrint National Park is located approximately 88 km away, encompassing a coastal wetland complex.

### 13.5.3.3 Fisheries restricted areas (FRAs)

The closest Fisheries Restricted Area to the project area is the Deep water fisheries restricted area (1,000 m), with its nearest boundary located approximately 9 km west/southwest from the exploration well. This FRA applies directly to portions of Block 2 where water depths exceed 1,000 m.

### 13.5.3.4 Forests and forested areas

The onshore support infrastructure of the Project is located entirely within the Port of Igoumenitisa, Municipal Unit of Igoumenitisa and not within the boundaries of the ratified and published forest map of Igoumenitisa (Initially Ratified Forest Map under Article 17 of Law 3889/2010 (as amended and in force), approved by GG 531/D/24 December 2018).

### 13.5.3.5 Water management plans

According to the 2nd Revision of the River Basin Management Plans for the Epirus River Basin District (EL05) approved by GG A' 71/17.05.2024, the study area lies within the Kalamas River Basin (EL0512). The marine zone includes the coastal water body "Igoumenitisa Bay" with code EL0512C0003H.

### 13.5.3.6 Flood risk management plans

According to 1st Revision of the Flood Risk Management Plan for the River Basin District of Epirus (EL05) was approved by Decision YPEN/DPDYP/61532/888 (GG 2775/B/05.06.2025), the study area falls within an Area of Potentially Significant Flood Risk named “Lower Reach – Delta of the Kalamas River and the Coastal Zone of Igoumenitsa”, with code EL05APSFR008 and an area of 70,5 km<sup>2</sup>.

### 13.5.4 Specific Emission Limit Values for Pollutant Loads and Concentrations According to Applicable Regulations

For ambient air quality levels, the following provisions apply:

- Joint Ministerial Decision (JMD) 14122/549/E103/24.3.2011 (GG B' 488): This decision establishes measures for the improvement of ambient air quality, in compliance with the provisions of Directive 2008/50/EC, as currently in force and amended.
- Joint Ministerial Decision (JMD) 22306/1075/E103/29.5.2007 (GG B' 920): This decision sets target values and assessment thresholds for the concentrations of arsenic, cadmium, mercury, nickel, and polycyclic aromatic hydrocarbons (PAHs) in ambient air, in compliance with the provisions of Directive 2004/107/EC, as currently in force and amended.
- Council of Ministers Act 25/18.3.88 (GG A' 52/22.3.88) and PYS 34/30.5.02 (GG A' 125/5.6.02), "Limit and guideline values for air quality regarding sulphur dioxide, nitrogen dioxide and nitrogen oxides, particulate matter, and lead."
- Presidential Decree 1180/81 (GG 293/A/1981) for point source emissions of solids (suspended particulates) from construction sites and project installations, the limit of 100 mg/m<sup>3</sup> established in Article 2, paragraph (d), applies.
- MARPOL Annex VI – Regulations for the Prevention of Air Pollution from Ships, sets limits on sulphur oxide and nitrogen oxide emissions from ship exhausts and prohibits deliberate emissions of ozone depleting substances.

For sewage from ships and other wastewater, the following apply:

- International Convention for the Prevention of Pollution from Ships, MARPOL 73/78
  - Annex I: Regulations for the Prevention of Pollution by Oil (Entered into force on October 2, 1983)
  - Annex IV: Prevention of Pollution from Ship Sewage (entered into force on September 27, 2003)
- Health Regulation No. E1β/221/1965 (GG B' 138), concerning the disposal of sewage and industrial wastewater, repealed by Law 4042/2012 (Article 59§2), but still referenced in practice for liquid effluent discharge limits per Circular No. οικ.191645/3.12.2013.

For waste from ships, and for solid and hazardous waste, the following apply:

- International Convention for the Prevention of Pollution from Ships, MARPOL 73/78, Annex V: Prevention of Pollution by Garbage from Ships (entered into force on December 31, 1998)
- For the management of used mineral oils, the provisions of Presidential Decree 82/2004 (GG A' 64/2.3.2004) apply, which replaced Joint Ministerial Decision 98012/2001/95 (GG B' 40/19-1-1996).
- For waste electrical and electronic equipment (WEEE), the provisions of Joint Ministerial Decision

23615/651/E.103/2014 (GG B' 1184) apply.

- For waste batteries and accumulators, the provisions of Joint Ministerial Decision 41624/2057/E103/2010 (GG B' 1625) apply.
- For source separation, collection, transport and management of solid waste, both recyclable and non-recyclable, the provisions of Law 4042/2012 (A' 24) as amended and in force, of the National Waste Management Plan ratified by Joint Ministerial Decision 51373/4684/2015 (B' 2706), and of Law 2939/2001 (A' 179) as amended by Law 4496/2017 (A' 170), apply.
- For source separation, collection, transport and management of hazardous waste, both recyclable and non-recyclable, the provisions of Law 4042/2012 (A' 24), as amended and in force, of the National Hazardous Waste Management Plan approved by Joint Ministerial Decision 62952/5384/2016 (B' 4326), and of Law 2939/2001 (A' 179) as amended by Law 4496/2017 (A' 170), apply.
- For the collection, transport and management of extractive waste, the provisions of Joint Ministerial Decision 39624/2209/E103/2009 "Measures, conditions and restrictions for the management of waste from the extractive industry in compliance with the provisions of Directive 2006/21/EC" apply.

The specific limit values for noise and vibration levels are determined by the following applicable regulations:

- Presidential Decree 57/2010 (GG 97/A/25.6.2010) – Adaptation of Greek Legislation to Directive 2006/42/EC of the European Parliament and of the Council “on machinery and amending Directive 95/16/EC,” repealing PDs 18/96 and 377/93, as amended by PD 81/2011 (GG 197/A/9.9.2011) “Amendment of PD 57/2010 (97/A) in compliance with Directive 2009/127/EC of the European Parliament and of the Council ‘amending Directive 2006/42/EC.’”
- JMD 56206/1613/86 (GG 570/B/1986) "Determination of the acoustic emission of construction site machinery and equipment in compliance with Directives 79/113/EEC, 81/1051/EEC, and 85/405/EEC of the Council of 19 December 1978, 7 December 1981, and 11 July 1985",
- JMD 69001/1921/88 (GG 751/B/1988) “EEC type approval for the noise level limit of construction machinery and equipment, specifically motorized air compressors, tower cranes, welding generator sets, power generator sets, and portable concrete breakers and pneumatic hammers,”
- Ministerial Decision 211773/2012 (GG 1367/B/2012), “Establishment of Evaluation Indicators and Maximum Permissible Limits of Environmental Noise Indicators resulting from the operation of transport infrastructure projects, technical specifications for special acoustic studies for the calculation and implementation (EAMYE) of noise barriers, specifications for environmental noise monitoring, and other provisions.”

## 13.6 Terms, measures and restrictions to be accounted for mitigation (prevention – minimization – remediation – restoration) of potential environmental impacts

### 13.6.1 General terms

The following environmental terms are proposed by the Project Operator for inclusion in the Environmental Terms Approval Decision (AEPO). Upon approval, the applicable environmental terms apply to Energean Hellas Ltd, as the Project Operator which will be responsible for complying with them.

They also apply to and must be followed by the contractors and by any natural or legal person assigned to carry out any part of the Project. All the above are referred to below as “third parties”.

When agreements are concluded between the Project Operator and third parties, as well as between third parties, they must include clear provisions requiring compliance with the environmental terms.

The Project Operator must take all necessary measures to ensure:

1. Compliance with the environmental terms by everyone involved in the Project and its supporting activities / operations.
2. The ability to respond to and restore situations that have an adverse effect on the environment as a result of acts or omissions that breach the environmental terms.
3. The Project Operator must comply with the applicable environmental legislation, whether or not it is specifically referred to in the environmental terms of the Project.
4. Project activities shall be carried out in accordance with the conditions of the existing operating permits, licences and land-use designations. Project activities at the Port of Igoumenitsa shall be carried out in accordance with the applicable Environmental Terms of the Port as amended and in force and tailored as needed within the present AEPO to support the specific workstreams.
5. Before any activity or installation needed to carry out the Project begins, all permits and approvals required under the applicable legislation must have been obtained.
6. When preparing the financial plan for the Project, the Project Operator must give priority to securing the funds required for environmental protection.
7. If works or activities are required as part of the Project that go beyond those covered by the Environmental Terms Approval Decision (AEPO) and described in the Environmental and Social Impact Assessment (ESIA), including any extension or modification of the Project, the procedure for amending the AEPO under Law 4014/2011 as in force and in accordance with Article 6 in case additional terms are deemed required or Article 7 in case minor adjustment(s) in accordance with final design of the operations, must be followed.
8. The Project Operator must establish an Environmental Unit, in the form of an organisational unit with an appropriate structure and position within the Project Operator’s organisation. The Environmental Unit will be responsible for the overall prevention, reduction and management of environmental impacts, including the following duties:
  - a. Monitoring compliance with the Environmental Terms.
  - b. Supervising and coordinating the implementation of environmental legislation.
  - c. Preparing proposals for measures and implementing programmes to meet the requirements of environmental legislation.
  - d. Environmental monitoring.
  - e. Liaising on all environmental matters with the local community, the internal organisational units of the Project Operator, third parties and the relevant public authorities.
9. The Project Operator must ensure that:

- a. The Environmental Unit has the responsibilities and authority, including an appropriate position within the organisational chart, needed to intervene effectively at all stages of the detailed design, implementation and decommissioning of the Project.
  - b. The duties of the Environmental Unit focus exclusively on environmental matters. These duties may be combined only with matters relating to the safety of the Project and its operations and/or the health and safety of personnel. The Unit must remain independent from other units within the Project Operator's organisational structure that carry out technical, administrative or financial duties.
  - c. The Environmental Unit is staffed with enough suitably qualified personnel and is provided by the Project Operator's management with the infrastructure and resources needed to operate effectively.
10. When the Project studies and designs are finalised, energy-saving measures, such as high-efficiency equipment must be included, where applicable.
  11. The Project Operator must provide any information requested by the Environmental Authority, namely the Directorate of Environmental Licensing (DIPA) of the Ministry of Environment and Energy, and the Hellenic Hydrocarbons and Energy Resources Management Company (HEREMA) throughout the duration of the Project.
  12. Before Project commencement, a comprehensive Environmental and Social Management Plan (ESMP) covering all works must be prepared. The ESMP shall be prepared and submitted for approval to DIPA where required by the applicable approval conditions and regulatory requirements. The results of its implementation must be submitted to DIPA at the end of the Project.

The EMP must include, in all cases:

- a. an analysis of how the environmental terms will be applied to all works and by all third parties involved;
- b. the way in which the monitoring and management programmes will be implemented, as well as the specifications of the related monitoring equipment;
- c. a review and assessment of how effectively the environmental terms have been applied to protect the natural and human environment, including the biodiversity, species and habitats of the area, as well as human economic activities, such as tourism and fisheries; and
- d. the results of the monitoring programme.

The conclusions of the ESMP will be used to determine whether there are any environmental impacts that were not identified in the original EIA and AEPO and whether additional terms must therefore be imposed or the original terms relating to demobilisation and abandonment must be amended.

## 13.6.2 Mobilization and drilling operations

### 13.6.2.1 Air quality, climatic and bioclimatic characteristics

---

13. Logistics activities, including support-vessel operations and the operation of onshore vehicles and machinery, shall be planned and managed by the relevant Contractors, in coordination with the Project Operator and the relevant facility operators. Such planning and management shall aim to minimise

unnecessary engine operation, idling and associated atmospheric emissions, to the extent permitted by operational and scheduling constraints.

14. All Project Contractors shall maintain the machinery, vessels and vehicles used for the Project in accordance with the manufacturers' specifications and maintenance schedules, in order to reduce exhaust emissions. Maintenance shall be carried out by the relevant contractor or owner at licensed onshore facilities, where practicable.
15. The Mobile Offshore Drilling Unit (MODU) and all Project support vessels shall comply with the requirements of MARPOL Annex VI, including the applicable fuel-quality and air-emission requirements relating to ozone-depleting substances, nitrogen oxides (NO<sub>x</sub>), sulphur oxides (SO<sub>x</sub>) and volatile organic compounds (VOCs).
16. The Project Operator shall coordinate with the relevant Contractors, the Port Authority and Corfu International Airport to optimise support-vessel and helicopter logistics through appropriate voyage and flight planning. Planning shall take account of the operational requirements of the drilling unit and shall aim to minimise vessel trips, the duration of activities within the Project area and unnecessary engine operation or idling, to the extent permitted by the operational constraints of the parties involved.
17. The Project Operator shall assess, in coordination with the operator of the Port of Igoumenitsa and the relevant vessel operators, whether existing shore-power facilities can be used by Project vessels while alongside. Shore power may be used where the existing infrastructure is available and compatible with the vessel and where the necessary technical, safety, operational and commercial arrangements have been agreed between the relevant parties. The Project shall not include the installation or substantial upgrading of shore-power infrastructure at the port.
18. LED lighting shall be used for internal lighting, where practicable, and unnecessary operation of external lighting shall be avoided.

#### 13.6.2.2 Morphology and Landscape

---

19. The Project shall use existing facilities at the Port of Igoumenitsa and Corfu International Airport (CFU). No new permanent onshore or offshore infrastructure, dredging, land reclamation or quay modifications shall be undertaken. All Project activities shall remain within designated operational areas. Onshore Project-support activities shall be carried out only within areas allocated or agreed for Project use by the relevant facility operator.
20. Project equipment, materials, vehicles and waste shall be stored, handled and parked only within designated areas, except while being transported in accordance with the applicable logistics and waste-management arrangements. Unauthorised disposal or storage outside the designated Project areas shall be prohibited.
21. The Project shall use the existing surfaced areas of the onshore logistics base. No additional permanent impermeable surfacing shall be constructed. If additional surfacing is subsequently required for the safe operation of the Project, it shall be limited to the minimum area necessary, shall be located within the area allocated for Project use and shall be subject to prior agreement with the Igoumenitsa Port operator and to any applicable approvals. Any reinstatement requirements shall also be agreed with

the Port operator.

22. During well operations at the Asopus-1 location, the MODU shall maintain its position using a dynamic-positioning system meeting IMO Dynamic Positioning Equipment Class 3 requirements or an equivalent Class 3 notation accepted by the relevant Flag State and classification society. Anchoring shall not be used for routine station-keeping during the drilling operations.

### 13.6.2.3 Waste and wastewater management

---

23. No hazardous waste shall be intentionally discharged into the marine environment.
24. Operational discharges, including drilling fluids and cuttings, sewage, bilge water, ballast water and food waste, shall be managed in accordance with applicable legal requirements.
25. Hazardous and non-hazardous waste generated offshore shall be segregated, stored, handled and transferred to authorised port-reception or waste-management facilities in accordance with the Project Waste Management Plan and the applicable requirements of MARPOL, Barcelona Convention and its Offshore Protocol, and applicable EU and Greek legislation.
26. Fuels, chemicals and any materials identified as hazardous under the applicable legislation or the relevant Safety Data Sheet shall be stored in designated areas at the logistics base.
27. Storage areas for fuels, chemicals and hazardous materials shall be provided with secondary containment and appropriate segregation, taking account of the nature and quantity of the materials and the associated spill risk.
28. Suitable spill-response materials and equipment shall be readily available at the relevant storage, transfer and handling locations, in accordance with the applicable site procedures and the Project spill-response arrangements.
29. Cementing discharges shall be managed in accordance with the Chemical Use Plan, the assessed discharge arrangements, the applicable regulatory requirements and, where relevant, the Waste Management Plan.
30. Unused, excess or waste pipe dope, contaminated rags or absorbents and empty containers shall be collected and segregated. Such materials shall be managed in accordance with the Project Waste Management Plan and the applicable MARPOL requirements and shall be transferred through the supply base to authorised onshore waste-management facilities.
31. Drilling cuttings and water-based drilling fluids discharged at the seabed during the riserless drilling sections shall be managed in accordance with the applicable regulatory requirements, including Barcelona Convention Offshore Protocol and the relevant UNEP/MAP Common Standards and Guidelines for the use and disposal of drilling fluids and cuttings in the Mediterranean.
32. Drilling cuttings and associated drilling fluids generated after installation of the marine riser shall be managed in accordance with the applicable regulatory requirements, including Barcelona Convention Offshore Protocol and the relevant UNEP/MAP Common Standards and Guidelines. Drilling returns shall be monitored through logging while drilling, mudlogging and routine observation.
33. Where cuttings or drilling returns are identified as mixed with reservoir hydrocarbons at concentrations

that make them unsuitable for discharge under the applicable requirements, discharge of the affected material shall cease immediately. The affected cuttings and fluids shall be contained onboard and transferred ashore for management at an authorised facility.

34. Sanitary wastewater, including blackwater and greywater, shall be managed and discharged in accordance with MARPOL Annex IV and the applicable Greek legislation. Blackwater shall be treated in an approved sewage-treatment system before discharge. Where the applicable discharge requirements cannot be met, sewage shall be retained in holding tanks and shall either be discharged once the applicable requirements can be met or be transferred to an authorised shore-reception facility.
35. Bilge water collected from machinery spaces shall be routed to dedicated bilge holding tanks, to be processed through the oily-water separator, fitted with a certified oil-content monitor and an automatic stopping device. The oily-water separator and oil-content monitor shall be type-approved in accordance with MARPOL Annex I and applicable MEPC.107(49) requirements, by the Flag State Administration or a Recognized Organization acting on its behalf. Treated bilge water may be discharged only where the oil content of the undiluted effluent does not exceed 15 mg/L or 15 ppm and all other applicable MARPOL Annex I discharge conditions are met.
36. Deck drainage from non-hazardous areas may be discharged through the vessel's drainage system. Any impacted runoff shall be contained and managed through the vessel's applicable drainage and treatment arrangements, including the oily-water separator, where applicable. Where oily deck drainage is treated through an oily-water separator, the oil content of the discharge shall not exceed 15 mg/L or 15 ppm. Deck drainage may be discharged into the sea only where discharge is permitted under the applicable MARPOL, Flag-State and vessel requirements and no visible oil sheen will result.
37. Cooling water shall be discharged through multiple outlets. The temperature difference between the cooling-water intake and discharge shall not exceed 5 °C. Cooling-water discharges shall be managed in accordance with the MODU's approved systems and procedures and the applicable environmental requirements. Cooling-water discharge shall consist of non-contact seawater and shall not contain oil or harmful substances.
38. Ballast water on the MODU and Project support or supply vessels shall be managed in accordance with:  
a. the Ballast Water Management Convention; b. Regulations B-1 and D-1 or D-2, as applicable; c. the approved Ballast Water Management Plan; and d. the Ballast Water Record Book. Any ballast-water management system installed onboard shall be type-approved by the Flag State Administration, or by a Recognized Organization acting on its behalf, in accordance with Regulation D-3 of the Ballast Water Management Convention.
39. Brine streams may be discharged only where they do not contain oil, harmful substances, or other contaminants introduced by machinery and waste streams. Brine discharges shall comply with the applicable MARPOL requirements, Greek environmental legislation and vessel procedures. Any discharge containing oil or oily residues shall be managed separately in accordance with MARPOL Annex
40. Food waste may be discharged only in accordance with the location and operational conditions applicable to the MODU and Project vessels under MARPOL Annex V, including the applicable minimum distance from the nearest land. Food waste intended for permitted discharge shall be comminuted or ground so that it can pass through a screen with openings no greater than 25 mm. Food waste mixed

with any other waste shall not be discharged into the sea.

41. No planned discharge from the MODU or Project vessels shall take place where, at the time of the proposed discharge, the vessel is located within: a. the Ionian Archipelago Important Marine Mammal Area; or b. the Nisoi Paxoi Kai Antipaxoi Kai Evryteri Thalassia Periochi Natura 2000 site, code GR2230003.

#### 13.6.2.4 Chemicals use and management

---

42. A Chemical Use Plan shall be implemented throughout drilling operations. The Chemical Use Plan shall include:
  43. the chemicals proposed for planned and contingency operations and the relevant environmental-hazard and ecotoxicity information;
  44. the purposes for which each chemical is intended to be used;
  45. the estimated concentrations and quantities of the chemicals intended to be used; and
  46. the potential routes and locations through which chemicals may be discharged into the marine environment, where applicable.
47. The selection, use and discharge of chemicals shall be controlled through the Project Chemical Use Plan. Drilling fluids, drilling cuttings and chemicals shall be managed in accordance with:
  48. the Project Chemical Use Plan;
  49. the Project Waste Management Plan;
  50. applicable regulatory requirements.
51. Only water-based drilling muds shall be used. No planned use of oil-based or other non-aqueous drilling fluids shall be permitted.
52. Preference shall be given, as applicable, to substances, drilling and cementing chemicals included on the PLONOR list and to products classified as CHARM Gold or OCNS Group E, where they are operationally suitable and available. Other chemicals may be used for planned or contingency operations only where a. their suitability has been reviewed; and b. no suitable lower-hazard alternative is reasonably available.
53. The use and discharge of substances covered by Annex I to the Barcelona Convention Offshore Protocol shall be prohibited, except where permitted under the applicable regulatory framework. Chemicals with higher-hazard classifications may be used only where: a. they are required to perform a specific technical function; and b. no suitable lower-hazard alternative is reasonably available.
54. No well-completion, stimulation or production-related chemicals shall be used as part of the Project.
55. Chemical transfer, storage and handling offshore shall be controlled through measures including, as applicable, appropriate containment, spill-prevention measures, bunding and closed-drainage systems, use of trained personnel and chemical inventory management.
56. Pipe dope and casing dope shall be treated as non-discharged chemicals. Their application shall be

controlled so as to minimise excess material and prevent any planned discharge into the sea. The use of pipe dope shall be controlled under the Chemical Use Plan, and pipe dope shall not be intentionally discharged into seawater. Any accidental spill of pipe dope shall be managed in accordance with the Project spill-response procedures.

#### 13.6.2.5 Noise and vibration

57. Material-handling and cargo operations at the logistics base shall be carried out by the relevant Contractors in accordance with the operating procedures of the Port of Igoumenitsa.
58. The drillship, support vessels, helicopters, generators and other relevant mechanical equipment shall be routinely inspected and maintained in accordance with the applicable maintenance programmes and manufacturers' recommendations. Equipment used for material-handling and cargo operations shall be maintained in good working order in order to minimise unnecessary noise emissions.
59. Support-vessel operations shall be coordinated by the Project Operator in cooperation with the relevant Contractors and taking account of the operational and safety requirements of the facility operator, the vessels and the drilling unit.
60. Support-vessel operations shall be planned, where reasonably practicable, so as to minimise underwater noise and unnecessary engine operation and idling.
61. All Vertical Seismic Profiling operations shall begin with a soft-start or ramp-up procedure, during which acoustic energy shall be increased gradually from low power to full operational power over a period of 20–30 minutes.
62. The soft-start procedure shall be implemented in accordance with the Marine Mammal Mitigation Plan.
63. The duration of Vertical Seismic Profiling operations shall be limited to the period reasonably necessary to achieve the survey objectives.

#### 13.6.2.6 Marine life, flora, fauna, habitats and protected areas

64. A Marine Mammal Mitigation Plan shall be prepared before the commencement of impulsive sound emissions. The Marine Mammal Mitigation Plan shall set out the mitigation protocol to be implemented by the relevant Contractors during the Vertical Seismic Profile operation. The mitigation protocol shall include visual monitoring by a qualified Marine Mammal Observer (MMO) and, where applicable, Passive Acoustic Monitoring, in order to detect marine mammals and manage the risk of injury from impulsive noise, continuously throughout VSP activities and optionally for the rest of the drilling campaign.
65. Before the commencement of Vertical Seismic Profiling operations, certified Marine Mammal Observers shall undertake a pre-shooting visual search for marine mammals and sea turtles within the 500 m mitigation zone specified in the Marine Mammal Mitigation Plan. The duration of the pre-shooting search and the applicable ramp-up, delay, shutdown and restart procedures shall be implemented in accordance with the Marine Mammal Mitigation Plan and the applicable regulatory requirements.
66. During Vertical Seismic Profiling operations, two Marine Mammal Observers holding ACCOBAMS

certification or an equivalent recognised qualification shall be positioned at suitable observation points onboard the vessel.

67. One or more suitably qualified Passive Acoustic Monitoring operators shall be provided where required under the Marine Mammal Mitigation Plan during Vertical Seismic Profile (VSP) operations if and such operation are carried out and are extended during the night, including for monitoring during darkness or poor visibility.
68. The following shall be recorded using the applicable reporting forms: a. marine-mammal sightings; b. sea-turtle sightings; c. pre-shooting searches; d. delays; e. soft-starts; f. shutdowns; and g. any other mitigation actions implemented. Monitoring records shall be submitted in accordance with the Marine Mammal Mitigation Plan.
69. All acoustic-source tests shall begin with a soft-start or ramp-up, gradually increasing acoustic energy from low power to full operational power over a period of 20–30 minutes. If a marine mammal or sea turtle is detected within the 500 m mitigation zone before the commencement of acoustic operations, the operations shall be delayed until the animal has left the mitigation zone and at least 20 minutes have elapsed since the last visual sighting, or any longer period specified in the Marine Mammal Mitigation Plan.
70. Within areas identified in the Marine Mammal Mitigation Plan as having a higher presence of marine mammals, Project vessels shall operate at speeds not exceeding 14 knots, or at their maximum operational speed where this is lower. The vessel-speed restriction shall apply provided that it does not compromise vessel safety or emergency-response capability.
71. Project vessels shall maintain a safe distance from any observed marine mammal. Project vessels shall not approach marine mammals head-on and shall avoid crossing or waiting ahead of their direction of travel. Where safe and practicable, vessels shall steer behind the animal's path.
72. In the event of a collision between a Project vessel and a marine mammal or sea turtle, the vessel Master shall immediately report the incident to the Project Operator in accordance with the Project incident-reporting procedure. Following such an incident, the Project Operator shall notify the competent environmental and other relevant authorities as soon as reasonably practicable and within any applicable regulatory timeframe, in accordance with the applicable legislation.
73. Project vessels shall follow established transit routes, where practicable, during drilling preparation and mobilisation. Vessel transit shall be undertaken in accordance with standard vessel-transit procedures, including the issue of applicable navigational notifications, such as NAVTEX messages, and coordination with the competent maritime authorities. The vessel Master may deviate from established routes where required for safety reasons.
74. Before spudding the well, a remotely operated vehicle survey shall be carried out within a radius of 70 m from the planned wellhead location to identify any pre-existing seabed features or sensitivities. If previously unidentified seabed features or sensitivities are identified within the surveyed area, the relevant competent authorities shall be informed.
75. Appropriate screens or equivalent protective measures shall be fitted to the drillship's seawater intakes in order to minimise the risk of entrainment of marine flora and fauna.

76. Light emissions shall be minimised during night-time hours, as far as practicable, while maintaining safe operations and compliance with navigational requirements. Directional lighting shall be used, where practicable, to minimise light spill onto the sea. External lighting shall comply with all applicable maritime, aviation, Flag-State and operational-safety requirements. Where practicable without affecting applicable safety requirements, non-essential external lighting shall be positioned, directed or shielded so as to minimise unnecessary upward and outward light spill, particularly during bird-migration periods. Where fitted, blinds or other available screening shall be used on accommodation windows during hours of darkness, where practicable, to minimise unnecessary outward light spill, particularly during bird-migration periods.
77. Helicopter flights shall be planned and carried out by the helicopter operator in accordance with applicable aviation requirements, air-traffic-control instructions and procedures. Where safe and operationally practicable, helicopter flight routes and altitudes shall be selected so as to avoid unnecessary overflight of known bird-breeding, roosting or concentration areas identified as relevant to the Project.

#### 13.6.2.7 Maritime uses and navigation

---

78. Subject to approval by the competent Greek authorities, a safety zone with a radius of 500 m around the MODU shall be established and officially notified for the duration of the well operations. Unauthorised access by vessels to the safety zone shall be restricted in accordance with the applicable authorisation and maritime notices. Information concerning the establishment and duration of the safety zone and the relevant operational details shall be communicated through official maritime-safety information channels. The relevant information shall include NAVTEX messages, navigational warnings and, where applicable, Notices to Mariners issued or coordinated by the Hellenic Navy Hydrographic Service in cooperation with the competent Hellenic Coast Guard authorities.
79. While on site, the Platform Supply Vessels (PSVs) shall assist the MODU, as required, in monitoring the safety zone and communicating with approaching vessels.
80. Before mobilisation and demobilisation, the Project Operator shall ensure that the drilling contractor liaises with the Hellenic Navy Hydrographic Service regarding the planned drilling and vessel-transit operations, in accordance with standard drilling-unit mobilisation procedures.
81. The main operators of cruise ships and LPG carriers identified through the Shipping and Navigation Assessment as regularly passing within or close to 500 m of the drilling location shall be informed in advance of the Asopus-1 operations. Such notification shall supplement the applicable official navigational notifications, including NAVTEX messages and Notices to Mariners, and shall enable vessel operators to review or amend their passage plans, where necessary.
82. The Offshore Installation Manager (OIM) and the Master of each support vessel shall have overriding authority and responsibility for decisions relating to safety and pollution prevention, in accordance with the International Safety Management Code.
83. The MODU and all Project support vessels shall comply with the applicable international and national maritime legislation, including COLREGs, and shall display the required lights, shapes and signals.

84. The owners or operators of the Platform Supply Vessels (PSVs) shall ensure that each vessel:
85. displays the applicable lights and marks;
86. operates the Automatic Identification System, where required; and
87. complies with the applicable international, Flag-State and coastal-State requirements, including Greek legislation, COLREGs and SOLAS.
88. Regular and timely communication shall be maintained throughout mobilisation with the Hellenic Coast Guard, relevant fisheries organisations, Port Authorities of Igoumenitsa and Corfu, the operator of Corfu International Airport and other key stakeholders identified by the Project.
89. Where practicable, mobilisation logistics at the Port of Igoumenitsa shall be scheduled in coordination with the Port Authority to minimise disruption to routine commercial and passenger operations at the port.
90. The MODU shall have a vessel-specific Collision Risk Management Plan informed by the site-specific Shipping and Navigation Assessment. The Collision Risk Management Plan shall address collision risks arising while the MODU is restricted in its ability to manoeuvre and engaged in well operations. The Collision Risk Management Plan shall include indicatevely and not exhaustively the following: a. measures to provide adequate warning time; b. continuous monitoring of marine traffic by competent watchkeeping personnel; c. use of AIS, ARPA and other available navigational aids; d. appropriate communications with approaching vessels; and e. display of the lights, shapes and signals corresponding to the MODU's operational status.

#### 13.6.2.8 Cultural Heritage

91. All project activities shall be governed principally by Law 4858/2021 (Code of Legislation for the Protection of Antiquities and Cultural Heritage) and informed by the principles of the UNESCO Convention on the Protection of the Underwater Cultural Heritage (2001) to ensure the appropriate management and, where practicable, in situ preservation of submerged archaeological resources.
92. Prior to the commencement of drilling activities, the Company shall submit to the Hellenic Ephorate of Underwater Antiquities the results of the detailed seabed survey of the marine area at the proposed Asopus-1 well location for review with respect to the potential presence of underwater cultural heritage. Based on the results of this review, and if deemed necessary by the Ephorate, an on-site underwater archaeological survey using technology (ROV, SSS, Sub bottom profiler shall be provided in the marine area where the exploration drilling is planned to take place. The cost of conducting this survey must be covered by the Project Owner.
93. Any additional geophysical, environmental or engineering datasets acquired before drilling that provide materially relevant new seabed information for areas subject to planned Project disturbance shall be reviewed to determine whether they materially change the archaeological baseline or require further archaeological assessment and/or notification to the Competent Authority.
94. Although no archaeological remains have been identified within the immediate Project footprint, the Chance Find Procedure shall be implemented if material of possible archaeological significance is encountered. The Chance Find Procedure shall include the following actions:

- 95. the affected activity shall be stopped to the extent necessary to avoid disturbance;
- 96. the location and nature of the suspected find shall be recorded;
- 97. practicable controls shall be applied to avoid further disturbance;
- 98. photographic or video documentation shall be obtained, where practicable;
- 99. advice shall be obtained from an appropriately qualified maritime archaeologist where required to support notification, preliminary interpretation or the response requested by the competent authority;
- 100. the designated Project representative shall notify the Ephorate of Underwater Antiquities within the timeframe required by applicable legislation and provide relevant information concerning the suspected find.

#### 13.6.2.9 Community and occupational health and safety

- 101. Appropriate personal protective equipment shall be provided to and used by all personnel where required by the task or work area, in accordance with the applicable procedures at the onshore logistics base and during marine operations. Project Operator and each Contractor shall be responsible for ensuring that its personnel comply with the Project requirements concerning personal protective equipment.
- 102. The Project Operator and each Contractor shall maintain appropriate personnel training and competence systems. Personnel shall receive Project-specific briefings on marine operations, traffic management and emergency response, as applicable.
- 103. Lifting operations shall be carried out by a Contractor qualified to perform lifting operations, using personnel with the required competence and qualifications.
- 104. Emergency-response drills shall be conducted at the intervals specified in the Project and vessel emergency-response procedures and in accordance with the applicable legal and Flag-State requirements. Emergency drills shall include, as applicable, fire-response, medical-evacuation, man-overboard and oil-spill-response exercises.
- 105. The Onshore Traffic Management Plan shall be reviewed/updated by the relevant logistics contractor once appointed. Any changes should be reviewed by the Port Authority and approved by the Project Operator prior to implementation. The Plan shall be updated during operations, as necessary, in response to relevant changes.
- 106. The installation of the temporary helicopter hangar and the associated helicopter operations at Corfu International Airport shall comply with the applicable civil-aviation safety procedures and the requirements of the airport operator.
- 107. The drillship shall maintain an Emergency Response Plan setting out the procedures to be followed in an emergency.
- 108. The MODU shall also maintain Well-Specific Operating Guidelines (WSOG) developed in accordance with IMCA M103 guidance for dynamically positioned drilling units and informed by the applicable station-keeping, riser and emergency-disconnect analyses. The Well-Specific Operating Guidelines shall

define: a. the applicable operating limits for the MODU; b. alert conditions and status levels; and c. the actions to be taken following loss or degradation of position. Where required by the WSOG and the associated MODU-procedures, the Emergency Disconnect Sequence (EDS) shall be initiated to secure the well and allow the MODU to disengage safely.

109. Sealed radioactive sources may be used only where required for formation-evaluation tools, including specific well-logging or logging-while-drilling tools. The use, storage and transport of sealed radioactive sources shall be managed by the relevant licensed Contractor in accordance with radiation-protection requirements and applicable authorisations of the Greek Atomic Energy Commission.

### 13.6.3 Demobilisation and abandonment

110. The exploration well shall be plugged and abandoned in accordance with the accepted Notification of Well Operations (NoWO), applicable regulatory requirements, the approved Plug and Abandonment (P&A) programme and Good International Industry Practice (GIIP), to provide long-term well integrity and prevent unintended releases to the marine environment.

#### 13.6.3.1 General decommissioning and site-restoration requirements

111. Plugging and abandonment shall be carried out so as to ensure long-term well integrity and prevent unintended releases into the marine environment.
112. Temporary subsea equipment deployed during the drilling campaign, including the marine riser, blowout preventer and acoustic-positioning transponders, shall be recovered following completion of the well operations.
113. Following plugging and abandonment and recovery of the temporary subsea equipment, a remotely operated vehicle seabed survey shall be carried out within a radius of 70 m from the well location.
114. The post-operation seabed survey shall identify any Project-related debris. Any non – cuttings related debris identified shall be documented and managed in accordance with the applicable operational and regulatory requirements.
115. Project equipment, materials, chemicals and waste remaining on the MODU or at the onshore support facilities after completion of their use shall be removed or otherwise managed in accordance with the Project Waste Management Plan. Materials shall be reused or recycled where reasonably practicable. Waste shall be transferred to authorised waste-management facilities.
116. Temporary Project facilities, equipment, signage and operational arrangements at the Port of Igoumenitsa and Corfu International Airport shall be removed, retained or otherwise managed in accordance with the arrangements agreed with the relevant facility operator. Areas used by the Project shall be left in the condition agreed with the relevant facility operator.
117. Records relating to plugging and abandonment, recovery of temporary subsea equipment, waste transfers and post-operation inspections shall be maintained. Such records shall be submitted to the competent authorities where required under the applicable regulatory requirements.
118. Permanent cement barriers shall be installed to provide long-term isolation of the well. The permanent

well barriers shall be verified using methods appropriate to the type of barrier and well conditions, according to the accepted Notification of Well Operations and approved well programme.

119. Following completion of the plugging and abandonment operations, the competent authorities (Hellenic Coast Guard, Port Authorities of Igoumenitsa and Corfu) and relevant marine users shall be informed of the departure of the MODU and the cessation of the Project activities.
120. Decommissioning and demobilisation activities shall be planned and coordinated with the relevant port and airport facility operators. Activity timing and arrangements shall, where reasonably practicable, be adjusted to minimise disruption to other facility users, without compromising safety, emergency-response, asset integrity or operational requirements.
121. Decommissioning and demobilisation activities shall be carried out so as to avoid unnecessary disruption to existing infrastructure and navigation routes, where reasonably practicable and without compromising safety, asset integrity, emergency response or operational requirements.
122. The Project Operator shall coordinate with the relevant Contractors, the Port Authority and Corfu International Airport to optimise support-vessel and helicopter logistics through appropriate voyage and flight planning.
123. Logistics planning shall take account of the operational requirements of the MODU and shall aim to minimise the number of vessel trips, reduce the duration of activities within the Project area and avoid unnecessary engine operation and idling. These measures shall be implemented to the extent permitted by the operational constraints of the parties involved.
124. Hazardous and non-hazardous waste generated offshore shall be identified, segregated, stored, handled and transferred to authorised port-reception or waste-management facilities. Waste management shall comply with:
  - the Project Waste Management Plan;
  - the applicable requirements of MARPOL;
  - the Barcelona Convention and its Offshore Protocol; and
  - applicable EU and Greek legislation.
125. No solid or hazardous waste shall be intentionally discharged into the marine environment.
126. Operational discharges, including drilling fluids and cuttings, sewage, bilge water, ballast water and food waste, shall be managed in accordance with applicable legal requirements.

#### 13.6.4 Minimization of environmental consequences from an incident or accidental release

##### 13.6.4.1 Emergency response plan

---

127. Before the commencement of drilling operations, the Project Operator shall prepare and maintain a Project Emergency Response Plan (ERP), which will be submitted and approved. It will cover foreseeable emergency scenarios associated with the Project. The Plan shall define the emergency-response organisation, roles and responsibilities, command and communication arrangements, notification and

escalation procedures, available response resources, coordination with Contractors and competent authorities, and procedures for evacuation, rescue, medical emergencies, well-control events, fire, explosion, toxic-gas releases, marine incidents, spills and other accidental releases.

128. The Emergency Response Plan (ERP) shall be coordinated with the applicable MODU and vessel emergency plans, including the Shipboard Oil Pollution Emergency Plan, and shall comply with the applicable international, EU, Greek, Flag-State and port-State requirements.

129. The Emergency Response Plan (EPR) shall be available throughout Project operations, communicated to relevant personnel and Contractors, and tested through regular drills and exercises. It shall be reviewed and updated following significant changes to the Project, changes to the assessed emergency scenarios, lessons identified through drills or incidents, or instructions issued by the competent authorities.

#### 13.6.4.2 Contingency activities triggered by unfavourable operational circumstances

---

130. Contingency activities shall be undertaken only in response to unforeseen technical, geological, well-integrity or operational conditions and in accordance with the approved well programme, the applicable management-of-change procedure and any regulatory notification, acceptance or environmental-permitting requirements.

131. Any contingency activity that falls outside the Project design envelope assessed in the Environmental Impact Assessment will not be undertaken unless any additional environmental assessment, permitting or approval requirements have first been completed, where applicable.

132. Where re-spudding or sidetracking is required, the affected section of the original wellbore shall be isolated using an appropriate well barrier or mechanical isolation system. Additional drilling fluids, cuttings, cement and waste generated shall be managed in accordance with the approved Chemical Use Plan, Waste Management Plan and applicable discharge requirements.

133. Where disconnection of the MODU from the well is required, the well shall be secured using the applicable well barriers and disconnection procedures before the MODU moves away from the well location.

134. Operations shall not resume following a failure or degradation of a well barrier until the affected barrier has been restored or replaced and its integrity has been verified.

135. Any release of drilling fluids, cuttings or other riser contents resulting from an emergency disconnection shall be recorded and reported to the competent authorities where required and shall be managed in accordance with the applicable emergency-response and environmental-monitoring procedures.

136. Tool components, severed tubulars and other materials arising from contingency operations shall be recovered where safe and technically practicable. Any material that cannot be recovered shall be documented and reported to the competent authority where required.

#### 13.6.4.3 Well-control and source-control arrangements

---

137. Well control shall be maintained through appropriate primary, secondary and, where required, tertiary

well-control measures in accordance with the approved well programme, the accepted Notification of Well Operations and the applicable well-control and well-integrity requirements.

138. Source-control arrangements proportionate to the assessed well-release scenarios shall be available throughout the drilling campaign and shall include as applicable, blowout-preventer intervention, subsea capping and relief-well arrangements.
139. In the event of a blowout or other loss of well control, drilling operations shall cease immediately, and the well shall be secured using the applicable well-control and emergency-isolation equipment. In the unlikely scenario where control cannot be restored, the applicable source-control arrangements defined in the Project Emergency Response Plan, Oil Spill Response Plan, and/or Source Control Emergency Response Plan shall be initiated.

#### 13.6.4.4 Spill and pollution response

---

140. Oil-pollution incidents shall be managed in accordance with the applicable Shipboard Oil Pollution Emergency Plan and the Project Emergency Response Plan.
141. Accidental releases of chemicals or hazardous substances shall be managed in accordance with the relevant vessel and Project emergency procedures, taking account of the substance released, its Safety Data Sheet and the nature and scale of the incident.
142. The source of any spill shall be controlled where safe and practicable, and the activity causing the release shall be suspended or isolated. Appropriate containment, recovery and environmental-protection measures shall be implemented without delay.
143. Where a spill exceeds the available onsite response capability, the competent authorities shall be notified without delay and additional response resources shall be mobilised in accordance with the applicable spill-response arrangements.
144. Chemical dispersants shall not be used without prior approval from the competent authority.
145. Environmental monitoring, waste management and surveillance of the affected area shall continue, as appropriate, until the competent response personnel determine that response and recovery operations have been completed.

#### 13.6.4.5 Marine navigation and collision risk

---

146. A vessel-specific Collision Risk Management Plan, based on the site-specific Shipping and Navigation Assessment, shall be implemented throughout the period during which the MODU is engaged in well operations.
147. Marine traffic around the MODU shall be continuously monitored by competent personnel using AIS, ARPA and other available navigational aids.
148. Where an imminent collision risk cannot be controlled through warnings or support-vessel intervention, the applicable dynamic-positioning, emergency-response and well-disconnection procedures shall be implemented.

#### 13.6.4.6 Loss of station-keeping

---

149. Loss or degradation of MODU station-keeping shall be managed in accordance with the approved Well-Specific Operating Guidelines and the applicable MODU procedures.

150. Where loss of station-keeping may affect well integrity or result in an accidental release, the well shall be secured and the MODU shall disconnect and move away from the well location.

#### 13.6.4.7 Radiological incidents

---

151. In the event of an incident involving a sealed radioactive source, the affected work shall cease immediately, the area shall be isolated and access shall be restricted.

152. The incident shall be managed by suitably qualified radiation-protection personnel in accordance with the licensed Contractor's approved procedures, the applicable radiation-protection legislation and the requirements of the Greek Atomic Energy Commission.

153. The competent authorities shall be notified within the period required by the applicable legislation and authorisations.

#### 13.6.4.8 Adverse Weather and Flooding

---

154. Weather conditions, wind forecasts and flood warnings relevant to offshore operations and onshore support facilities shall be monitored throughout the Project.

155. Lifting operations, vessel transfers, offshore personnel transfers and helicopter operations shall be postponed, suspended or rescheduled where the applicable weather-related operating limits are approached or exceeded.

156. Where adverse weather is forecast or encountered that may exceed, or are expected to exceed, the applicable operational limits, the well shall be placed in a safe condition and Project equipment, chemicals and hazardous materials shall be secured or protected, in accordance with the applicable MODU procedures and Well-Specific Operating Guidelines (WSOG).

157. Project-critical equipment, electrical systems, chemicals and hazardous materials at the Port of Igoumenitsa and Corfu International Airport shall be located or protected taking account of the applicable flood risk.

158. Where forecast or actual flooding may affect Project operations, mobile equipment, chemicals and hazardous materials shall be secured, protected or relocated, and access and logistics arrangements shall be reviewed in coordination with the relevant facility operator.

### 13.6.5 Monitoring

---

An Environmental and Social Monitoring Programme shall be implemented throughout the Project activities in order to verify compliance with the applicable environmental requirements and monitor the effectiveness

of the mitigation measures. The detailed Programme, its implementation means and its timeline for execution, is presented in detail in Table 12-4 of Chapter 12.2.2 of the present ESIA.

The Monitoring Plan for the Asopus-1 Exploration Drilling Project in Block 2 will be fully aligned with all applicable legal, regulatory, and international industry standards and best practices, as well as the provisions set out in YPEN SEA Approval No. 30373/2017.

Should new legal or regulatory obligations emerge, the Environmental and Social Monitoring Plan will be extended or adapted accordingly.

The proposed Environmental and Social Monitoring Plan for the Project, covering applicable compliance monitoring and environmental-effects monitoring during the drilling preparation and mobilisation, drilling, and decommissioning/abandonment phases.

The findings of the ESMP during the implementation of the Project will be summarized in an Environmental and Social Monitoring Report, which should be formulated in a way that is understandable to the public and made public via the internet. The report will be communicated to the Ministry of Environment and Energy, which exercises responsibilities for environmental licensing, environmental inspection and control, as well as management of biodiversity and protected areas.

Records relating to environmental monitoring, plugging and abandonment, subsea-equipment recovery, waste transfers and post-operation inspections shall be retained and submitted to the competent authorities where required.

Where monitoring identifies non-compliance or ineffective mitigation, proportionate corrective actions shall be implemented.

### **13.7 Duration of validity of the environmental terms approval decision – Conditions for renewal and modifications**

1. The environmental terms of this decision are valid for fifteen (15) years from the date of its issuance, subject to Article 2, paragraphs 8a and 9 of Law 4014/2011 (GG 209/A') as in force, and Article 1, paragraph 1 of Law 4685/2020 (GG 92/A'), provided that there is no change in the conditions on the basis of which it was issued. Its validity may be extended for six (6) years if the project has an Environmental Management System based on the "Eco-Management and Audit Scheme" (EMAS) standards, for as long as the System remains in force, and for four (4) years if the project has an Environmental Management System certified under ISO 14001 or another equivalent standard, for as long as the System remains in force. For the above extensions, a relevant certification act is issued. Failure to timely renew the above Environmental Management Systems results, during the period of such extensions, in the automatic expiration of the Environmental Terms Approval Decision (AEPO). Additionally, the project operator is required to maintain a valid Environmental Management System for at least one (1) year prior to the expiration of the AEPO renewal deadline.
2. Before the expiration of this period, the project operator must initiate the process for the renewal of the environmental terms, as specified in Article 5 of Law 4014/2011, as in force. According to the same

article, if the renewal dossier is submitted on time (at least two months prior to the expiration of validity), the environmental terms remain in effect for the period until the completion of the renewal process.

3. Compliance with Article 6 and/or Article 7 of Law 4014/2011, as in force, is required for the any modification or specialisation following operations design finalisation of the project activities and its support operations, as described in Section 1 of this decision and implemented in accordance with the Environmental Terms.
4. In the event that regular or extraordinary environmental inspections identify serious environmental degradation issues, or if environmental impacts not anticipated in the ESIA and this decision are observed, additional environmental terms shall be imposed or the terms of this decision shall be modified, as provided in paragraph 9 of Article 2 of Law 4014/2011, as in force, in conjunction with Article 6 of the same law.

### 13.8 Other provisions

---

This decision:

1. Does not cover safety issues, which continue to be regulated by the existing relevant provisions, including those of Law 4409/2016 (A' 136).
2. Does not exempt the project proponent from the obligation to obtain any other permits, approvals, or regulatory acts required by the applicable legislation for the project.

### 13.9 Obligations regarding the monitoring of compliance with environmental terms

---

1. This decision and the accompanying Environmental Impact Assessment (EIA), as well as any future files regarding renewals, amendments, or technical environmental studies along with the relevant decisions, must be available on the project site. These documents must be presented by the responsible project operator to any competent authority or inspection body, in accordance with the applicable legislation.

The project operator, both during the implementation phase and during the decommissioning phase, must:

- 1.1. Maintain records that demonstrate compliance with the environmental terms of the project (e.g., contracts, supporting documents, invoices, data registries, electronic files, etc.).
- 1.2. Allow access to the project site for any competent inspection authority and facilitate the conduct of inspections.
- 1.3. Provide all required documents and information.
- 1.4. Facilitate inspections and comply with the recommendations or instructions of the competent authorities responsible for enforcing environmental legislation.
- 1.5. If issues arise during the implementation of this decision that are not covered by its terms, their resolution shall be carried out in accordance with the applicable legislation, and where this is not possible, based on the approved project studies or any future files related to the project's environmental permitting.

2. In the event of pollution or any other environmental degradation, or a violation of the terms of this decision, the project operators shall be subject to the penalties provided for in Articles 28, 29, and 30 of Law 1650/1986, as amended and currently in force.
